

# FP Foundations, Scheme

In Text: Chapter 11

## Outline

- Mathematical foundations
- Functional programming
- $\lambda$ -calculus
- LISP
- Scheme

## Imperative Languages

- We have been discussing imperative languages
  - C/C++, Java, and Pascal are imperative languages
  - They follow the von Neuman architecture [1]

3

## Functional Programming

- A different way of looking at things
  - It is based on mathematical functions
  - It is supported by functional, and applicative, programming languages
    - LISP, ML, Haskell

## Mathematical Foundations

- A **mathematical function** is a mapping of members from one set to another set
  - The "input" set is called the **domain**
  - The "output" set is called the **range**
- A mathematical function defines a value, rather than specifying a sequence of operations on values in memory to produce a value

N. Meng, S. Arthur

5

## Mathematical Foundations

- The evaluation order of mapping expressions is controlled by **recursion and conditional expressions**, rather than by the sequencing and iterative repetition
- Functions do not have states
  - They have no side effects
  - They always produce the same output given the same input parameters

N. Meng, S. Arthur

6

## Simple Functions

- Usual form:  
function name + a list of parameters in parentheses + mapping expression
- E.g.,  $\text{cube}(x) = x * x * x$ , where
  - both the domain and range sets are real numbers, and
  - $x$  can represent any member of the domain set, but it is fixed to represent one specific element during the expression evaluation

N. Meng, S. Arthur

7

## Function Application

- It is specified by pairing the function name with a particular element of the domain set
- The range element is obtained by evaluating the function-mapping expression with the domain element substituted for the particular element
  - $\text{Cube}(2.0) = 2.0 * 2.0 * 2.0 = 8.0$

N. Meng, S. Arthur

8

## Functional Forms

- A higher-order function, or **functional form**, is one that either takes functions as parameters, or yields a function as its result, or both
- Two common functional forms
  - Function composition
  - Apply-to-all

N. Meng, S. Arthur

9

## Function Composition

- **Function composition** has **two functional parameters** and **yields a function** whose value is the first function applied to the result of the second
- It is written as an expression, using a  $\circ$  operator (called "circle" or "round")
  - E.g.,  $h = f \circ g$   
 if  $f(x) = x + 2$ , and  
 $g(x) = 3 * x$   
 then  $h(x) = f(g(x)) = (3 * x) + 2$

N. Meng, S. Arthur

10

## Apply-to-all

- **Apply-to-all** takes a **single function** as a parameter
- If applied to a list of arguments, apply-to-all applies its functional parameter to each element of the list, and then collects results in a list or sequence
- It is denoted by  $\alpha$ 
  - E.g.,  $h(x) = x * x$ , then  
 $\alpha(h, (2, 3, 4)) = (4, 9, 16)$

N. Meng, S. Arthur

11

## Lambda expression

- Early theoretical work on functions separated the task of defining a function from that of naming the function
- Lambda notation,  $\lambda$ , provides a method for defining nameless functions
- A **lambda expression** is a function, which specifies the parameters, and the mapping expression
  - E.g.,  $\lambda(x)x * x * x$

N. Meng, S. Arthur

12

## Lambda-Calculus

- In the mid 1960s, Peter Landin observed that a complex programming language can be understood by formulating it as a tiny core calculus capturing the language's essential mechanisms, together with a collection of convenient derived forms whose behavior is understood by translating them into the core

N. Meng, S. Arthur

13

## Lambda-Calculus

- The core language used by Landin was the lambda-calculus, a formal system invented in the 1920s by Alonzo Church in which all computation is reduced to the basic operations of function definition and application

N. Meng, S. Arthur

14

## factorial Example

- factorial(n) =  
if n = 0 then 1 else n \* factorial(n - 1)
- The corresponding  $\lambda$ -calculus term is:  
factorial(n) =  
 $\lambda n. \text{if } n=0 \text{ then } 1 \text{ else } n * \text{factorial}(n - 1)$
- Meaning
  - For each nonnegative number n, instantiating the function with the argument n yields the factorial of n as result

N. Meng, S. Arthur

15

## $\lambda$ -calculus

- Lambda-calculus embodies function definition and application in the purest possible form
- In the lambda-calculus, everything is a function
  - the arguments accepted by functions are themselves functions, and
  - the result returned by a function is another function

N. Meng, S. Arthur

16

## Syntax of $\lambda$ -calculus

- $t ::= x$  (a variable)  
 $\quad | \lambda x.t$  (a function)  
 $\quad | t t$  (function application)
- The syntax of lambda-calculus comprises three sorts of terms
    - Variable itself is a term
    - The abstraction of a variable  $x$  from a term  $t$  is a term
    - The application of term  $t_1$  to another term  $t_2$ , is a term

N. Meng, S. Arthur

17

## Two conventions of writing lambda-terms

- Application is left associative
  - Given  $s t u$ , the calculation is  $(s t) u$

N. Meng, S. Arthur

18

## Two Conventions

- The body of abstraction is extended to right as much as possible
  - Given  $\lambda x. \lambda y. x y x$ , the calculation is  $\lambda x. (\lambda y. ((x y) x))$

N. Meng, S. Arthur

19

## Scope

- An occurrence of the variable  $x$  is said to be bound when it occurs in the body  $t$  of an abstraction  $\lambda x. t$
- An occurrence of  $x$  is free if it appears in a position where it is not bound by an enclosing abstraction on  $x$ 
  - In  $x y$ , and  $\lambda y. x y$ ,  $x$  is free
  - In  $\lambda x. x$ , and  $\lambda z. \lambda x. \lambda y. x (y z)$ ,  $x$  is bound

N. Meng, S. Arthur
