

Program Syntax

In Text: Chapter 3 & 4

Overview

- Basic concepts
 - Programming language, regular expression, context-free grammars
- Lexical analysis
 - Scanner
- Syntactic analysis
 - Parser

2

What is a "Language"?

- A language is a set of strings of symbols that are constrained by rules
- A **sentence** is a string of symbols
- A *language* is a set of sentences

3

What is a "Language"?

- **Syntax** and **semantics** provide a language's definition
 - **Syntax** (Grammar)
 - To describe the structure of a language
 - **Semantics**
 - To describe the meaning of sentences, phrases, or words

4

Formal Definition of Languages

- Recognizers
 - A recognition device reads input strings over the alphabet of the language and decides whether the input strings belong to the language
 - Example: syntax analysis part of a compiler
- Generators
 - A device that generates sentences of a language

5

Natural Languages Are Ambiguous

- "I saw a man on a hill with a telescope"
- Programming languages should be precise and unambiguous
 - Both programmers and computers can tell what a program is supposed to do

6

Programming Language Definition

- Syntax
 - To describe what its programs look like
 - Specified using **regular expressions** and **context-free grammars**
- Semantics
 - To describe what its programs mean
 - Specified using axiomatic semantics, operational semantics, or denotational semantics

7

Regular Expressions

- A regular expression is one of the following:
 - A character
 - The empty string, denoted by ϵ
 - Two or more regular expressions concatenated
 - Two or more regular expressions separated by | (or)
 - A regular expression followed by the Kleene star (concatenation of zero or more strings)

8

Regular Expressions

- The pattern of numeric constants can be represented as:

$digit \rightarrow 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9$
 $unsigned_integer \rightarrow digit\ digit^*$
 $unsigned_number \rightarrow unsigned_integer ((\cdot unsigned_integer) | \epsilon)$
 $(((e | E) (+ | - | \epsilon) unsigned_integer) | \epsilon)$

9

What is the meaning of following expressions ?

- $[0-9a-f]^+$
- $b[aeiou]^+t$
- $a^*(ba^*ba^*)^*$

10

Define Regular Expressions

- Match strings only consisting of 'a', 'b', or 'c' characters
- Match only the strings "Buy more milk", "Buy more bread", or "Buy more juice"
- Match identifiers which contain letters and digits, starting with a letter

11

Context-Free Grammars

- Context-Free Grammars
 - Developed by Noam Chomsky in the mid-1950s
 - Describe the syntax of natural languages
 - Define a class of languages called context-free languages
 - Was originally designed for natural languages

12

Context-Free Grammars

- Using the notation Backus-Naur Form (BNF)
- A context-free grammar consists of
 - A set of *terminals* T
 - A set of *non-terminals* N
 - A *start symbol* S (a non-terminal)
 - A set of *productions* P

13

Terminals T

- The basic symbols from which strings are formed
- Terminals are tokens
 - if, foo, -, 'a'

14

Non-terminals N

- Syntactic variables that denote sets of strings or classes of syntactic structures
 - expr, stmt
- Impose a hierarchical structure on the language

15

Start Symbol S

- One nonterminal
- Denote the language defined by the grammar

16

Production P

- Specify the manner in which terminals and nonterminals are combined to form strings
- Each production has the format
nonterminal \rightarrow a string of nonterminals and terminals
- One nonterminal can be defined by a list of nonterminals and terminals

17

Production P

- Nonterminal symbols can have more than one distinct definition, representing all possible syntactic forms in the language

```
<if_stmt>  $\rightarrow$  if <logic_expr> then <stmt>
<if_stmt>  $\rightarrow$  if <logic_expr> then <stmt> else <stmt>
```

Or

```
<if_stmt>  $\rightarrow$  if <logic_expr> then <stmt>
| if <logic_expr> then <stmt> else <stmt>
```

18

Backus-Naur Form

- Invented by John Backus and Peter Naur to describe syntax of Algol 58/60
- Used to describe the context-free grammars
- A **meta-language**: a language used to describe another language

19

BNF Rules

- A rule has a left-hand side(LHS), one or more right-hand side (RHS), and consists of **terminal** and **nonterminal** symbols
- For a nonterminal, when there is more than one RHS, there are multiple alternative ways to expand/replace the nonterminal
 - E.g., `<stmt> -> <single_stmt>`
 `| begin <stmt_list> end`

20

BNF Rules

- Rules can be defined using recursion

```
<ident_list> -> ident
               | ident, <ident_list>
```
- Two types of recursion
 - Left recursion:
 - `id_list_prefix -> id_list_prefix, id | id`
 - Right recursion
 - The above example

21

How does BNF work?

- It is like a mathematical game:
 - You start with a symbol **S**
 - You are given rules (**Ps**) describing how you can replace the symbol with other symbols (**Ts** or **Ns**)
 - The language defined by the BNF grammar is the set of all terminal strings (**sentences**) you can produce by following these rules

22

Derivation

- A grammar is a generative device for defining languages
- The sentences of the language are generated through a sequence of rule applications
- The sequence of rule applications is called a **derivation**

23

An Example Grammar

```
<program> -> <stmts>
<stmts>   -> <stmt>
           | <stmt> ; <stmts>
<stmt>   -> <var> = <expr>
<var>    -> a | b | c | d
<expr>   -> <term> + <term>
           | <term> - <term>
<term>   -> <var>
           | const
```

24

An Exemplar Derivation

```

<program> => <stmts>
           => <stmt>
           => <var> = <expr>
           => a = <expr>
           => a = <term> + <term>
           => a = <var> + <term>
           => a = b + <term>
           => a = b + const ← sentence

```

25

Sentential Forms

- Every string of symbols in the derivation is a **sentential form**
- A **sentence** is a sentential form that has only terminal symbols
- A **leftmost derivation** is one in which the leftmost non-terminal in each sentential form is the one that is expanded next in the derivation

26

Sentential Forms

- A **left-sentential form** is a sentential form that occurs in the leftmost derivation
- A **rightmost derivation** works right to left instead
- A **right-sentential form** is a sentential form that occurs in the rightmost derivation
- Some derivations are neither leftmost nor rightmost

27

Why BNF?

- Provides a clear and concise syntax description
- The parse tree can be generated from BNF
- Parsers can be based on BNF and are easy to maintain

28

Context-Free Grammars

- The syntax of simple arithmetic expression

```

expr -> id | number | -expr | (expr)
      | expr op expr
op -> + | - | * | /

```
- What are the terminal symbols and nonterminal symbols?
- What is the start symbol?

29

One Possible Derivation

```

expr => expr op expr
     => ...
     => id + number

```

30

Parse Tree

- A **parse tree** is
 - a hierarchical representation of a derivation
 - to represent the structure of the derivation of a terminal string from some non-terminal
 - to describe the hierarchical syntactic structure of programs for any language

31

An Example

- Given the simple assignment statement syntax

```

            <assign> -> <id> = <expr>
            <id> -> A | B | C
            <expr> -> <id> + <expr>
                    | <id> * <expr>
                    | ( <expr> )
                    | <id>
            
```
- With leftmost derivation, how is $A = B * (A + C)$ generated?

32

Derivation for $A = B * (A + C)$

```

<assign> => <id> = <expr>
=> A = <expr>
=> A = <id> * <expr>
=> A = B * <expr>
=> A = B * ( <expr> )
=> A = B * ( <id> + <expr> )
=> A = B * ( A + <expr> )
=> A = B * ( A + <id> )
=> A = B * ( A + C )
    
```

33

The Parse Tree for $A = B * (A + C)$

34

Parse Tree

- A grammar is **ambiguous** if it generates a sentential form that has two or more distinct parse trees

35

An Ambiguous Grammar

```

expr -> id | number | -expr | (expr)
      | expr op expr
op -> + | - | * | /
    
```

- Parse trees for "slope * x + intercept":

36

What goes wrong?

- The production rules do not capture the **associativity** and **precedence** of various operators
 - **Associativity** tells whether the operators group left to right or right to left
 - Is $10 - 4 - 3$ equal to $(10 - 4) - 3$ or $10 - (4 - 3)$?
 - **Precedence** tells that some operators group more tightly than the others
 - Is $\text{slope} * x + \text{intercept}$ equal to $(\text{slope} * x) + \text{intercept}$ or $\text{slope} * (x + \text{intercept})$?

37

Operator Associativity

- Single recursion in production rules
 - $\langle \text{expr} \rangle \rightarrow \langle \text{expr} \rangle - \langle \text{expr} \rangle \mid \text{const}$
 ✗ **Ambiguous**
 - $\langle \text{expr} \rangle \rightarrow \langle \text{expr} \rangle - \text{const} \mid \text{const}$
 ✓ **Unambiguous**
 - $\langle \text{expr} \rangle \rightarrow \text{const} - \langle \text{expr} \rangle \mid \text{const}$
 ✓ **Unambiguous (less desirable)**

38

Operator Precedence

- Use stratification in production rules
 - Intentionally put operators at different levels of parse trees
- ```

<expr> -> <expr> - <term> | <term>
<term> -> <term> / const | const

```

39

### Improved Unambiguous Context-Free Grammar

- $\text{expr} \rightarrow \text{expr add\_op term} \mid \text{term}$
- $\text{term} \rightarrow \text{term mul\_op factor} \mid \text{factor}$
- $\text{factor} \rightarrow \text{id} \mid \text{number} \mid \text{-factor} \mid (\text{expr})$
- $\text{add\_op} \rightarrow + \mid -$
- $\text{mul\_op} \rightarrow * \mid /$

40

### Revisit "slope \* x + intercept"

- Parse Tree

41

### Extended BNF (EBNF)

- There are extensions of BNF to simplify representation
  - Kleene star  $*$  or  $\{\}$  to represent repetition (0 or more)
  - $()$  to represent alternative parts
  - $[]$  to represent optional parts
    - $\text{proc\_call} \rightarrow \text{id}(['\text{expr\_list}'])$

42

## BNF and EBNF

- BNF

```
<expr> → <expr> + <term>
 | <expr> - <term>
 | <term>
<term> → <term> * <factor>
 | <term> / <factor>
 | <factor>
```

- EBNF

```
<expr> → <term> {(+ | -) <term>}
<term> → <factor> {(* | /) <factor>}
```

43

## Homework 2

- Due date: 12:30pm on 10/11

44
