

STATIC SEMANTICS

Attribute Grammar

- A device used to describe more of the structure of a programming language than can be described with a context-free grammar
- It provides a formal framework for decorating parse trees
- An attribute grammar is an extension to a context-free grammar

Attribute Grammar

- The extension includes
 - Attributes
 - Attribute computation functions
 - Predicate functions

A Running Example

- Context-Free Grammar (CFG)

```
<assign> -> <var> = <expr>  
<expr>   -> <var> + <var>  
<expr>   -> <var>  
<var>    -> A | B | C
```

- Note:

- It only focuses on potential structured sequence of tokens
- It says nothing about the meaning of any particular program

Attributes

- Associated with each grammar symbol X is a set of attributes $A(X)$. The set $A(X)$ consists of two disjoint sets: $S(X)$ and $I(X)$

Attributes

- $S(X)$: synthesized attributes, which are used to pass semantic information up a parse tree

Attributes

- $I(X)$: inherited attributes, which pass semantic information down or across a tree. They are similar to variables because they can also have values assigned to them

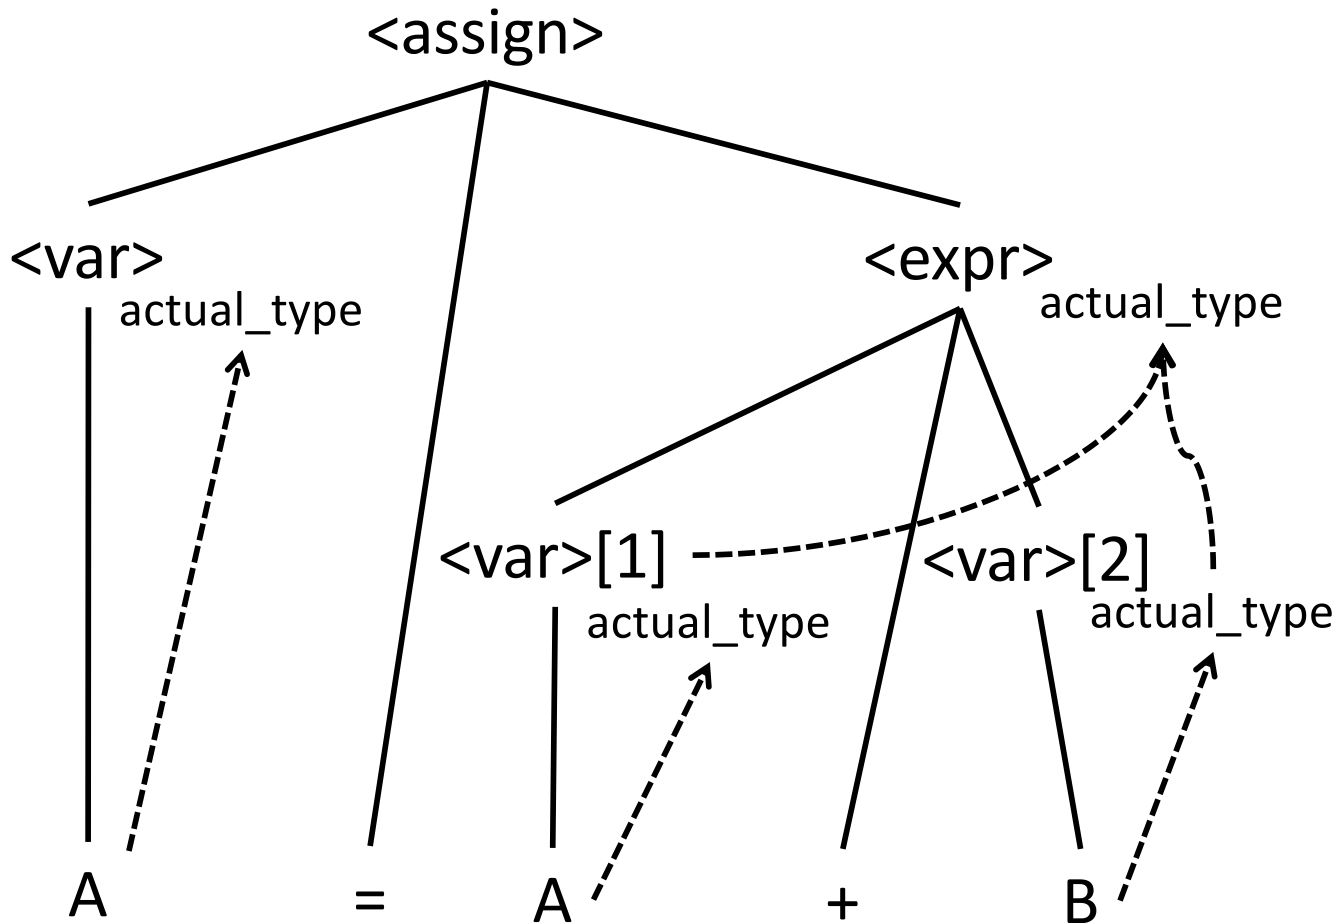

Intrinsic Attributes

- Synthesized attributes of leaf nodes whose values are determined outside the parse tree
 - E.g., the type of a variable can come from the symbol table
 - Given the intrinsic attribute values on a parse tree, the semantic functions can be used to compute the remaining attribute values

Example Synthesized Attribute

- *actual_type*
 - A synthesized attribute associated with nonterminals: `<var>` and `<expr>`
 - It is used to store the actual type, int or real, of a variable or expression
 - The attribute is determined by the actual types of children nodes

Evaluation Order of Synthesized Attribute *actual_type*

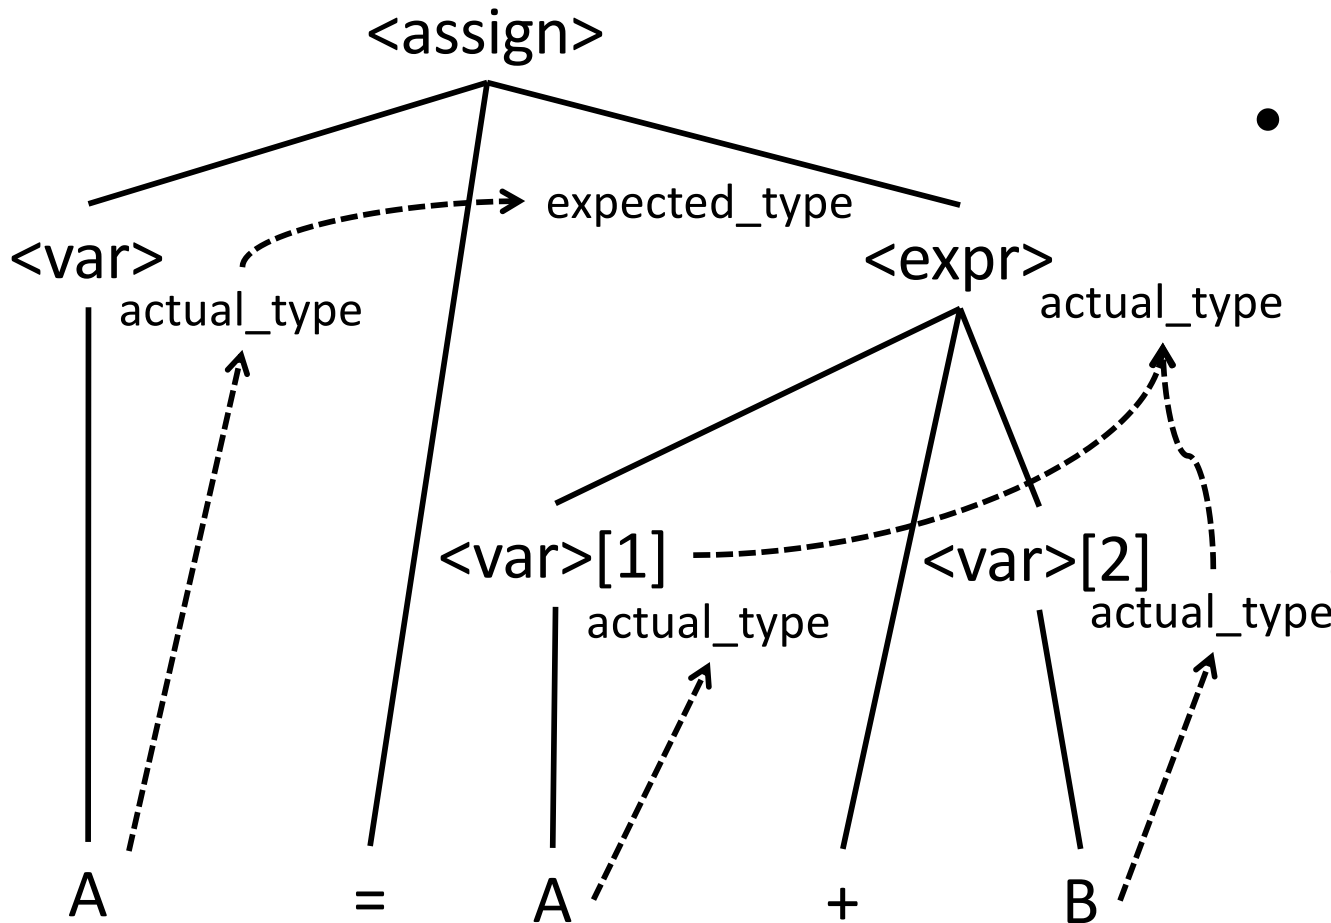

- Parser tree of $A = A + B$
- A and B have type "real" or "int" according to the symbol table

Example Inherited Attribute

- *expected_type*
 - An inherited attribute associated with the nonterminal `<expr>`
 - It is used to store the expected type, either `int` or `real`
 - It is determined by the type of the variable on the left side of the assignment statement

Evaluation Order of Inherited Attribute *expected_type*

- The *expected_type* of `<expr>` is decided by the *actual_type* of the assignment's left side

Attribute Grammar

- Defines the attributes, and attribute evaluation rules mentioned in the example

Example Attribute Grammar

Syntax Rule	Semantic Rule
$\langle \text{assign} \rangle \rightarrow \langle \text{var} \rangle = \langle \text{expr} \rangle$	R1. $\langle \text{expr} \rangle.\text{expected_type} \leftarrow \langle \text{var} \rangle.\text{actual_type}$
$\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle[1] + \text{var}[2]$	R2. $\langle \text{expr} \rangle.\text{actual_type} \leftarrow$ if ($\langle \text{var} \rangle[1].\text{actual_type} = \text{int}$) and ($\langle \text{var} \rangle[2].\text{actual_type} = \text{int}$) then int else real end if predicate: $\langle \text{expr} \rangle.\text{actual_type} == \langle \text{expr} \rangle.\text{expected_type}$
$\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle$	R3. $\langle \text{expr} \rangle.\text{actual_type} \leftarrow \langle \text{var} \rangle.\text{actual_type}$ predicate: $\langle \text{expr} \rangle.\text{actual_type} == \langle \text{expr} \rangle.\text{expected_type}$
$\langle \text{var} \rangle \rightarrow A \mid B \mid C$	R4. $\langle \text{var} \rangle.\text{actual_type} \leftarrow \text{look-up}(\langle \text{var} \rangle.\text{string})$ The look-up function looks up a given variable name in the symbol table and returns the variable's type

Semantic Functions

- Specify how attribute values are computed for $S(X)$ and $I(X)$

Semantic Functions

- For a rule $X_0 \rightarrow X_1 \dots X_n$, the synthesized attributes of X_0 are computed with semantic functions of the form $S(X_0) = f(A(X_1), \dots, A(X_n))$

Semantic Functions

- Inherited attributes of symbols X_j , $1 \leq j \leq n$, are computed with a semantic function of the form $I(X_j) = f(A(X_0), \dots, A(X_n))$
- To avoid circularity, inherited attributes are often restricted to functions of the form $I(X_j) = f(A(X_0), \dots, A(X_{j-1}))$

Revisit the Semantic Functions

Syntax Rule	Semantic Rule
$\langle \text{assign} \rangle \rightarrow \langle \text{var} \rangle = \langle \text{expr} \rangle$	1. $\langle \text{expr} \rangle.\text{expected_type} \leftarrow \langle \text{var} \rangle.\text{actual_type}$
$\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle[1] + \text{var}[2]$	2. $\langle \text{expr} \rangle.\text{actual_type} \leftarrow$ if ($\langle \text{var} \rangle[1].\text{actual_type} = \text{int}$) and $(\langle \text{var} \rangle[2].\text{actual_type} = \text{int})$ then int else real end if
$\langle \text{expr} \rangle \rightarrow \langle \text{var} \rangle$	3. $\langle \text{expr} \rangle.\text{actual_type} \leftarrow \langle \text{var} \rangle.\text{actual_type}$
$\langle \text{var} \rangle \rightarrow A \mid B \mid C$	4. $\langle \text{var} \rangle.\text{actual_type} \leftarrow \text{look-up}(\langle \text{var} \rangle.\text{string})$ The look-up function looks up a given variable name in the symbol table and returns the variable's type

Predicate Function

- A predicate function has the form of a Boolean expression on the union of the attribute set $\{A(X_0), \dots, A(X_n)\}$, and a set of literal attribute values
- A false predicate function value indicates a violation of the syntax or static semantic rules

Example Semantic Rules & Predicates

Syntax Rule	Semantic Rule
<code><assign> -> <var> = <expr></code>	R1. <code><expr>.expected_type <- <var>.actual_type</code>
<code><expr> -> <var>[1] + var[2]</code>	R2. <code><expr>.actual_type <- if (<var>[1].actual_type = int) and (<var>[2].actual_type = int) then int else real end if</code> predicate: <code><expr>.actual_type == <expr>.expected_type</code>
<code><expr> -> <var></code>	R3. <code><expr>.actual_type <- <var>.actual_type</code> predicate: <code><expr>.actual_type == <expr>.expected_type</code>
<code><var> -> A B C</code>	R4. <code><var>.actual_type <- look-up(<var>.string)</code> The look-up function looks up a given variable name in the symbol table and returns the variable's type

Another Example: Constant Expressions

- CFG

$E \rightarrow E + T$

$E \rightarrow E - T$

$E \rightarrow T$

$T \rightarrow T * F$

$T \rightarrow T / F$

$T \rightarrow F$

$F \rightarrow - F$

$F \rightarrow (E)$

$F \rightarrow \text{const}$

Note:

- Says nothing about the meaning of any **particular** program
- Conveys only potential structured sequence of tokens

Example Attribute Grammar

- Attribute: val
- Semantic Rules

$E_1 \rightarrow E_2 + T$	$E1.val = E2.val + T.val$
$E_1 \rightarrow E_2 - T$	$E1.val = E2.val - T.val$
$E \rightarrow T$	$E.val = T.val$
$T_1 \rightarrow T_2 * F$	$T1.val = T2.val * F.val$
$T_1 \rightarrow T_2 / F$	$T1.val = T2.val / F.val$
$T \rightarrow F$	$T.val = F.val$
$F_1 \rightarrow - F_2$	$F1.val = - F2.val$
$F \rightarrow (E)$	$F.val = E.val$
$F \rightarrow \text{const}$	$F.val = C.val$

Evaluating Attributes

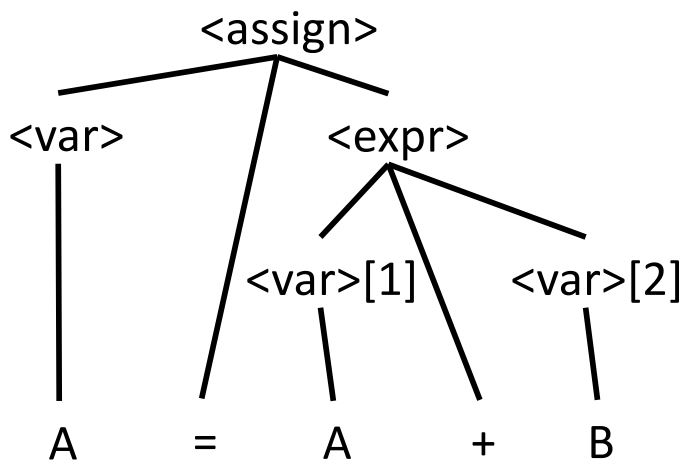

- The process of **evaluating** attributes is called annotation, or DECORATION, of the parse tree
- If all attributes are inherited, the evaluation process can be done in a top-down order
- Alternatively, if all attributes are synthesized, the evaluation can proceed in a bottom-up order

An Example Parse Tree

- We have both inherited and synthesized attributes. In what direction should we proceed the computation?

An Example Parse Tree

R1. $\langle \text{expr} \rangle . \text{expected_type} \leftarrow \langle \text{var} \rangle . \text{actual_type}$

R2. $\langle \text{expr} \rangle . \text{actual_type} \leftarrow \text{if} (\langle \text{var} \rangle [1] . \text{actual_type} = \text{int}) \text{ and}$
 $\quad (\langle \text{var} \rangle [2] . \text{actual_type} = \text{int})$
 then int
 else real
 end if

predicate: $\langle \text{expr} \rangle . \text{actual_type} == \langle \text{expr} \rangle . \text{expected_type}$

R3. $\langle \text{expr} \rangle . \text{actual_type} \leftarrow \langle \text{var} \rangle . \text{actual_type}$

predicate: $\langle \text{expr} \rangle . \text{actual_type} == \langle \text{expr} \rangle . \text{expected_type}$

R4. $\langle \text{var} \rangle . \text{actual_type} \leftarrow \text{look-up}(\langle \text{var} \rangle . \text{string})$

The look-up function looks up a given variable name in the symbol table and returns the variable's type

1. $\langle \text{var} \rangle . \text{actual_type} \leftarrow \text{look-up}(A) \text{ (R4)}$
2. $\langle \text{expr} \rangle . \text{expected_type} \leftarrow \langle \text{var} \rangle . \text{actual_type} \text{ (R1)}$
3. $\langle \text{var} \rangle [1] . \text{actual_type} \leftarrow \text{look-up}(A) \text{ (R4)}$
 $\langle \text{var} \rangle [2] . \text{actual_type} \leftarrow \text{look-up}(B) \text{ (R4)}$
4. $\langle \text{expr} \rangle . \text{actual_type} \leftarrow \text{either int or real} \text{ (R2)}$
5. $\langle \text{expr} \rangle . \text{expected_type} == \langle \text{expr} \rangle . \text{actual_type}$ is either TRUE or FALSE (R2)

Attribute Evaluation Order

- Determining attribute evaluation order for any attribute grammar is a complex problem, requiring the construction of a dependency graph to show all attribute dependencies

Decoration of a parse tree for $(1 + 3) * 2$

$E \rightarrow E + T$

$E \rightarrow E - T$

$E \rightarrow T$

$T \rightarrow T * F$

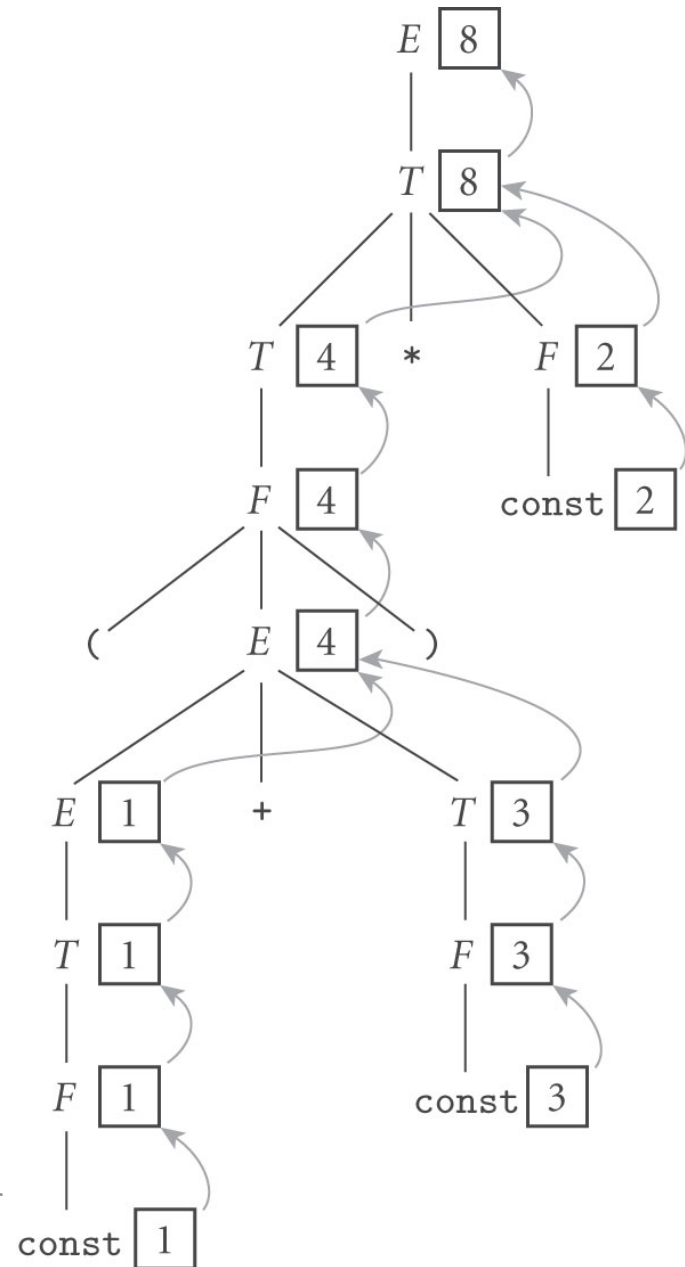

$T \rightarrow T / F$

$T \rightarrow F$

$F \rightarrow - F$

$F \rightarrow (E)$

$F \rightarrow \text{const}$

A Third Example of Attribute Grammar

- CFG

`expr -> const expr_tail`

`expr_tail -> -const expr_tail | ϵ`

- What is the parse tree of $9 - 4 - 3$?
- Can we accumulate the values of the overall expression into the root of the tree?

Insight

- We need to parse attribute values not only bottom-up, but also top-down and left-to-right in the tree

Attribute Grammar for Constant Expressions based on LL(1) CFG

- $E \rightarrow T TT$
 - $\triangleright TT.st := T.val$
 - $\triangleright E.val := TT.val$
- $TT_1 \rightarrow + T TT_2$
 - $\triangleright TT_2.st := TT_1.st + T.val$
 - $\triangleright TT_1.val := TT_2.val$
- $TT_1 \rightarrow - T TT_2$
 - $\triangleright TT_2.st := TT_1.st - T.val$
 - $\triangleright TT_1.val := TT_2.val$
- $TT \rightarrow \epsilon$
 - $\triangleright TT.val := TT.st$
- $T \rightarrow F FT$
 - $\triangleright FT.st := F.val$
 - $\triangleright T.val := FT.val$
- $FT_1 \rightarrow * F FT_2$
 - $\triangleright FT_2.st := FT_1.st \times F.val$
 - $\triangleright FT_1.val := FT_2.val$
- $FT_1 \rightarrow / F FT_2$
 - $\triangleright FT_2.st := FT_1.st \div F.val$
 - $\triangleright FT_1.val := FT_2.val$
- $FT \rightarrow \epsilon$
 - $\triangleright FT.val := FT.st$
- $F_1 \rightarrow - F_2$
 - $\triangleright F_1.val := - F_2.val$
- $F \rightarrow (E)$
 - $\triangleright F.val := E.val$
- $F \rightarrow \text{const}$
 - $\triangleright F.val := \text{const.val}$

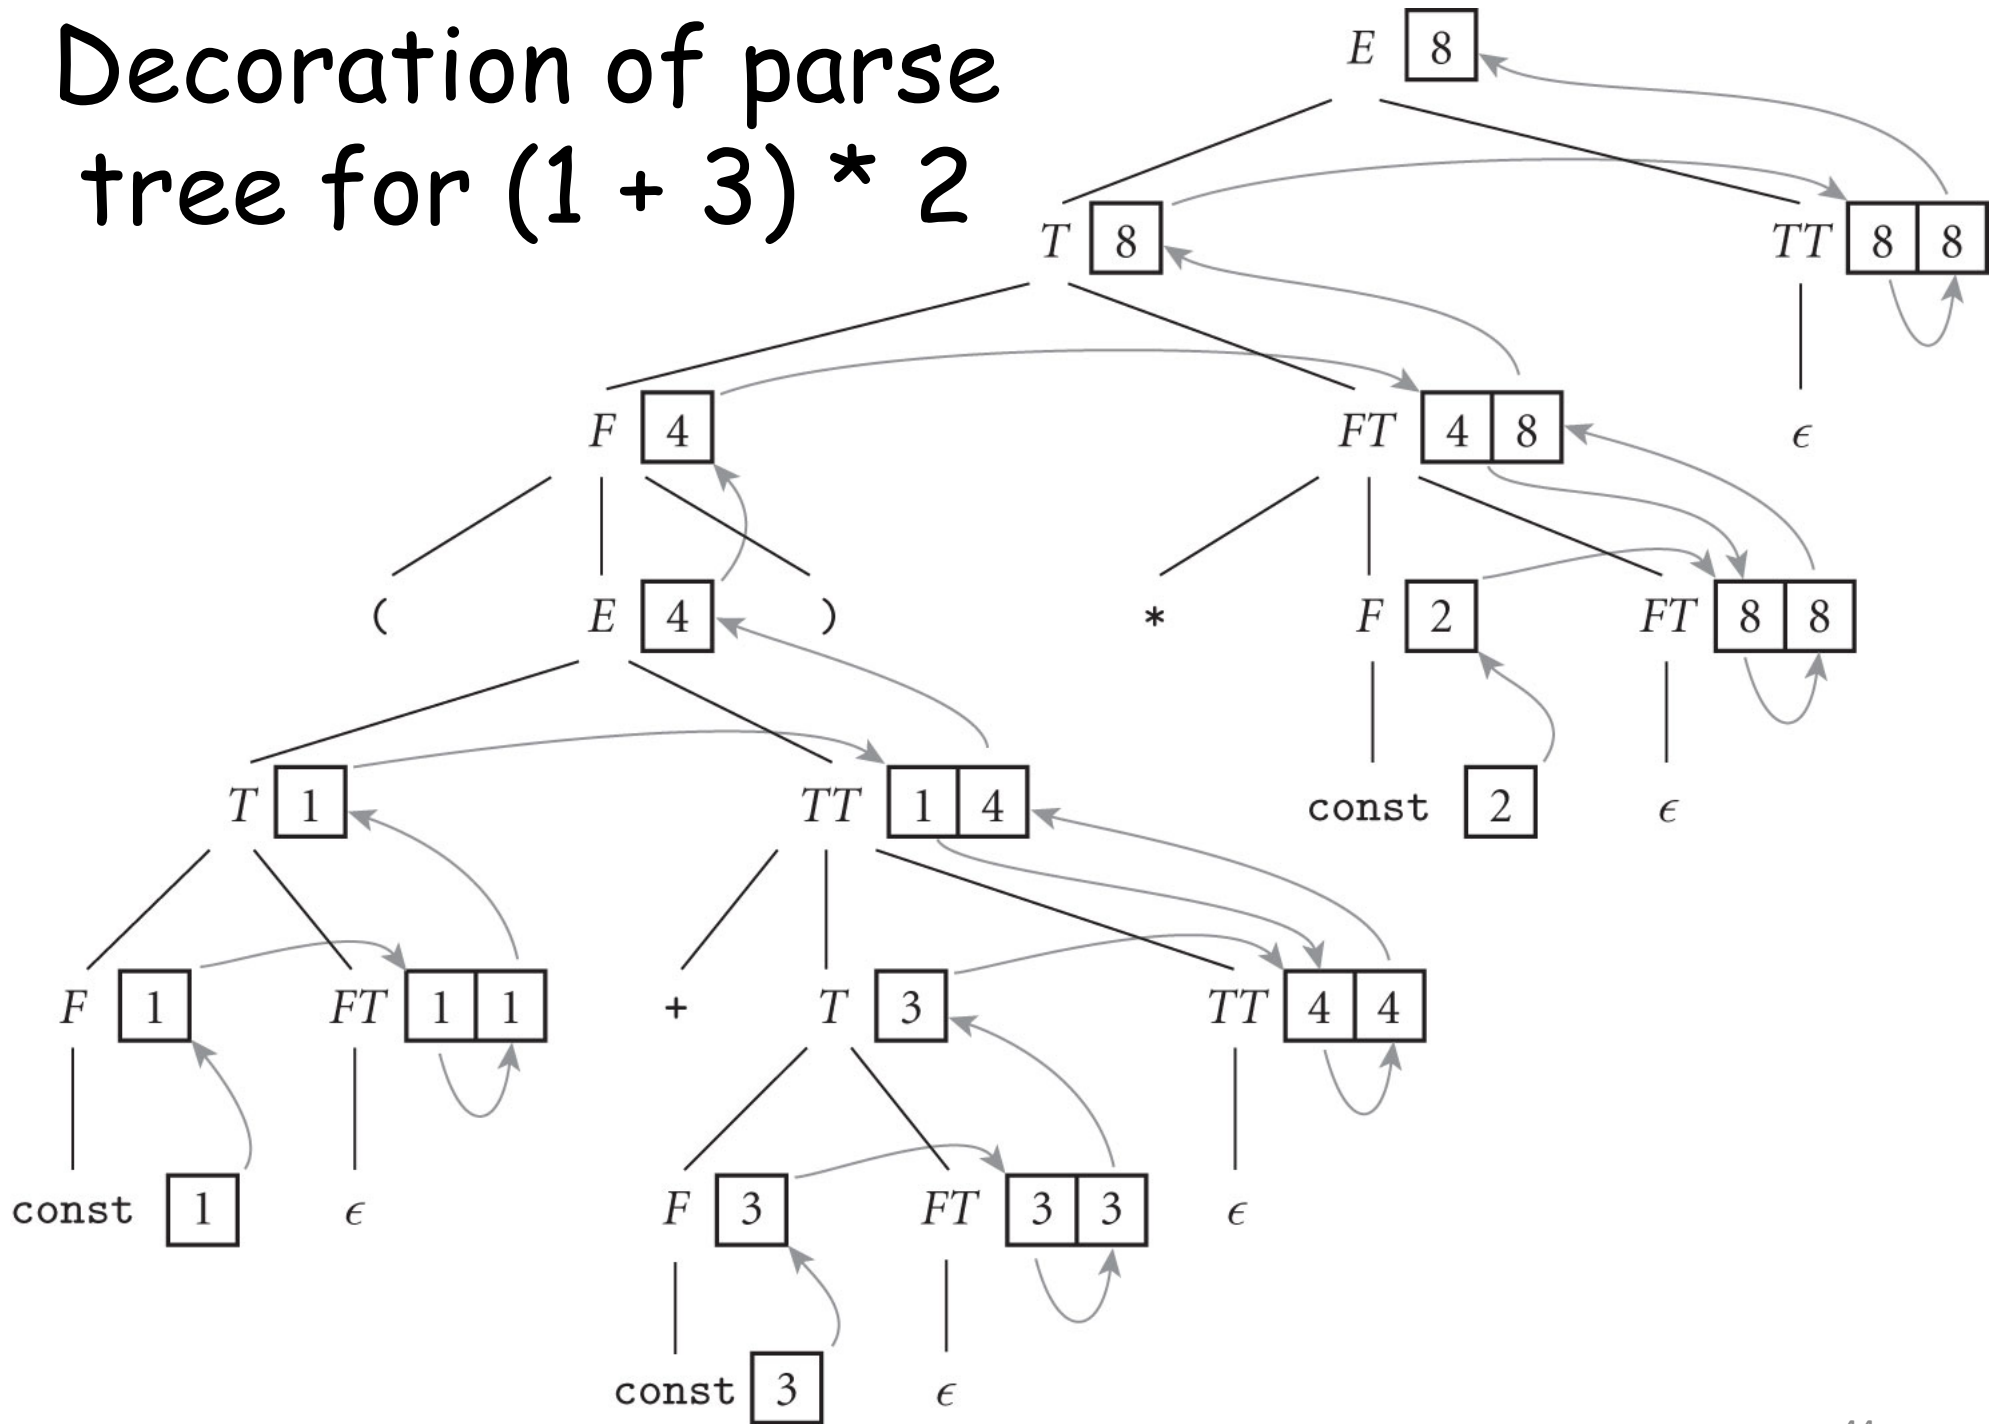

Attribute Grammar for CE LL(1) CFG

- Attributes
 - *st*: subtotal attribute to record intermediate evaluation result so far
 - *val*: value attribute to copy the right-most leaf back up to the root

Decoration of $(1 + 3) * 2$

1. $E \longrightarrow T TT$
 - ▷ $TT.st := T.val$ ▷ $E.val := TT.val$
2. $TT_1 \longrightarrow + T TT_2$
 - ▷ $TT_2.st := TT_1.st + T.val$ ▷ $TT_1.val := TT_2.val$
3. $TT_1 \longrightarrow - T TT_2$
 - ▷ $TT_2.st := TT_1.st - T.val$ ▷ $TT_1.val := TT_2.val$
4. $TT \longrightarrow \epsilon$
 - ▷ $TT.val := TT.st$
5. $T \longrightarrow F FT$
 - ▷ $FT.st := F.val$ ▷ $T.val := FT.val$
6. $FT_1 \longrightarrow * F FT_2$
 - ▷ $FT_2.st := FT_1.st \times F.val$ ▷ $FT_1.val := FT_2.val$
7. $FT_1 \longrightarrow / F FT_2$
 - ▷ $FT_2.st := FT_1.st \div F.val$ ▷ $FT_1.val := FT_2.val$
8. $FT \longrightarrow \epsilon$
 - ▷ $FT.val := FT.st$
9. $F_1 \longrightarrow - F_2$
 - ▷ $F_1.val := - F_2.val$
10. $F \longrightarrow (E)$
 - ▷ $F.val := E.val$
11. $F \longrightarrow \text{const}$
 - ▷ $F.val := \text{const.val}$

Decoration of parse tree for $(1 + 3) * 2$

Program Assignment 2

- Bitwise Manipulation of Hexidecimal Numbers

- CFG
 - `E → E "|" A` bitwise OR
 - `E → A`
 - `A → A "^" B` bitwise XOR
 - `A → B`
 - `B → B "&" C` bitwise AND
 - `B → C`
 - `C → "<" C` bitwise shift left 1
 - `C → ">" C` bitwise shift right 1
 - `C → "~" C` bitwise NOT
 - `C → "(" E ")"`
 - `C → hex`

LL(1) Attribute Grammar

$E \rightarrow A EE$
 $EE.st = A.val \quad E.val = EE.val$

$EE_1 \rightarrow | A EE_2$
 $EE_2.st = EE_1.st | A.val \quad (\text{"|"} \text{ bitwise OR})$
 $EE_1.val = EE_2.val$

$EE \rightarrow \epsilon$
 $EE.val = EE.st$

$A \rightarrow B AA$
 $AA.st = B.val \quad A.val = AA.val$

$AA_1 \rightarrow ^ B AA_2$
 $AA_2.st = AA_1.st ^ B.val \quad (\text{"^"} \text{ bitwise XOR})$
 $AA_1.val = AA_2.val$

$AA \rightarrow \epsilon$
 $AA.val = AA.st$

$B \rightarrow C BB$
 $BB.st = C.val \quad B.val = BB.val$

$BB_1 \rightarrow \& C BB_2$
 $BB_2.st = BB_1.st \& C.val \quad (\text{"\&"} \text{ bitwise AND})$
 $BB_1.val = BB_2.val$

$BB \rightarrow \epsilon$
 $BB.val = BB.st$

$C_1 \rightarrow < C_2$
 $C_1.val = C_2.val \ll 1 \quad (\text{"\<<"} \text{ bitwise shift left one})$

$C_1 \rightarrow > C_2$
 $C_1.val = C_2.val \gg 1 \quad (\text{"\>>"} \text{ bitwise shift right one})$

$C_1 \rightarrow \sim C_2$
 $C_1.val = \sim C_2.val \quad (\text{"\sim"} \text{ bitwise NOT})$

$C \rightarrow (E)$
 $C.val = E.val$

$C \rightarrow \text{hex}$
 $C.val = \text{hex.val}$

Program Requirement

- Write a C program using recursive descent parser w/ lexical analyzer to implement the designated inherited and synthesized attributes. The program evaluates the expressions in a file input.txt, and outputs the results to console
- E.g., input: f&a
output: f&a = a

Program Requirements

- You cannot use more than 2 global/non-local variables, and they should be to hold the Operator and HexNumber as detected by the lexical analyzer

Hints

- To solve the problems, you should take the following steps:
 - Write a lexical analyzer
 - Write a recursive-descent parser
 - Attributes are processed as either pass-in parameters or return value of functions

Hints

- Write a lexical analyzer
 - You may need to define an enum type for all possible tokens your scanner can generate
 - E.g., when reading hexadecimal numbers 0-9 or a-f, the recognized token is HEX, and the value is saved in HexNumber

Hints

- Write a recursive-descent parser
 - Parse the program by defining and invoking functions
 - E.g., $E \rightarrow A EE$
 $EE.st = A.val \quad E.val = EE.val$

```
int E() {  
    int val = A();  
    return EE(val);  
}
```

Hints

- There are parameters passed in or returned when invoking functions. When invoking a function, the synthesized attribute is the return value, while the inherited attribute is the passing-in parameter

Hints

- Sample code of main()

```
int main() {
    int val;
    symbol = getNextToken();
    while (symbol != EOF_) {
        if (symbol != NEW_LINE) {
            val = E();
            printf(" = %x\n", val & 0xf);
        }
        if (symbol == EOF_) break;
        symbol = getNextToken();
    }
    return 1;
}
```

Submission Requirements

- Pack the following files into a .tar file:
 - Source file: parser.c
 - Executable file: parser
 - Input file: input.txt
 - Output file: output.txt (copy all your console outputs to this file)
 - README file (optional, used if you have any additional comments/explanations about the files)
