

Machine Learning

Intro to AI
Bert Huang
Virginia Tech

Machine Learning

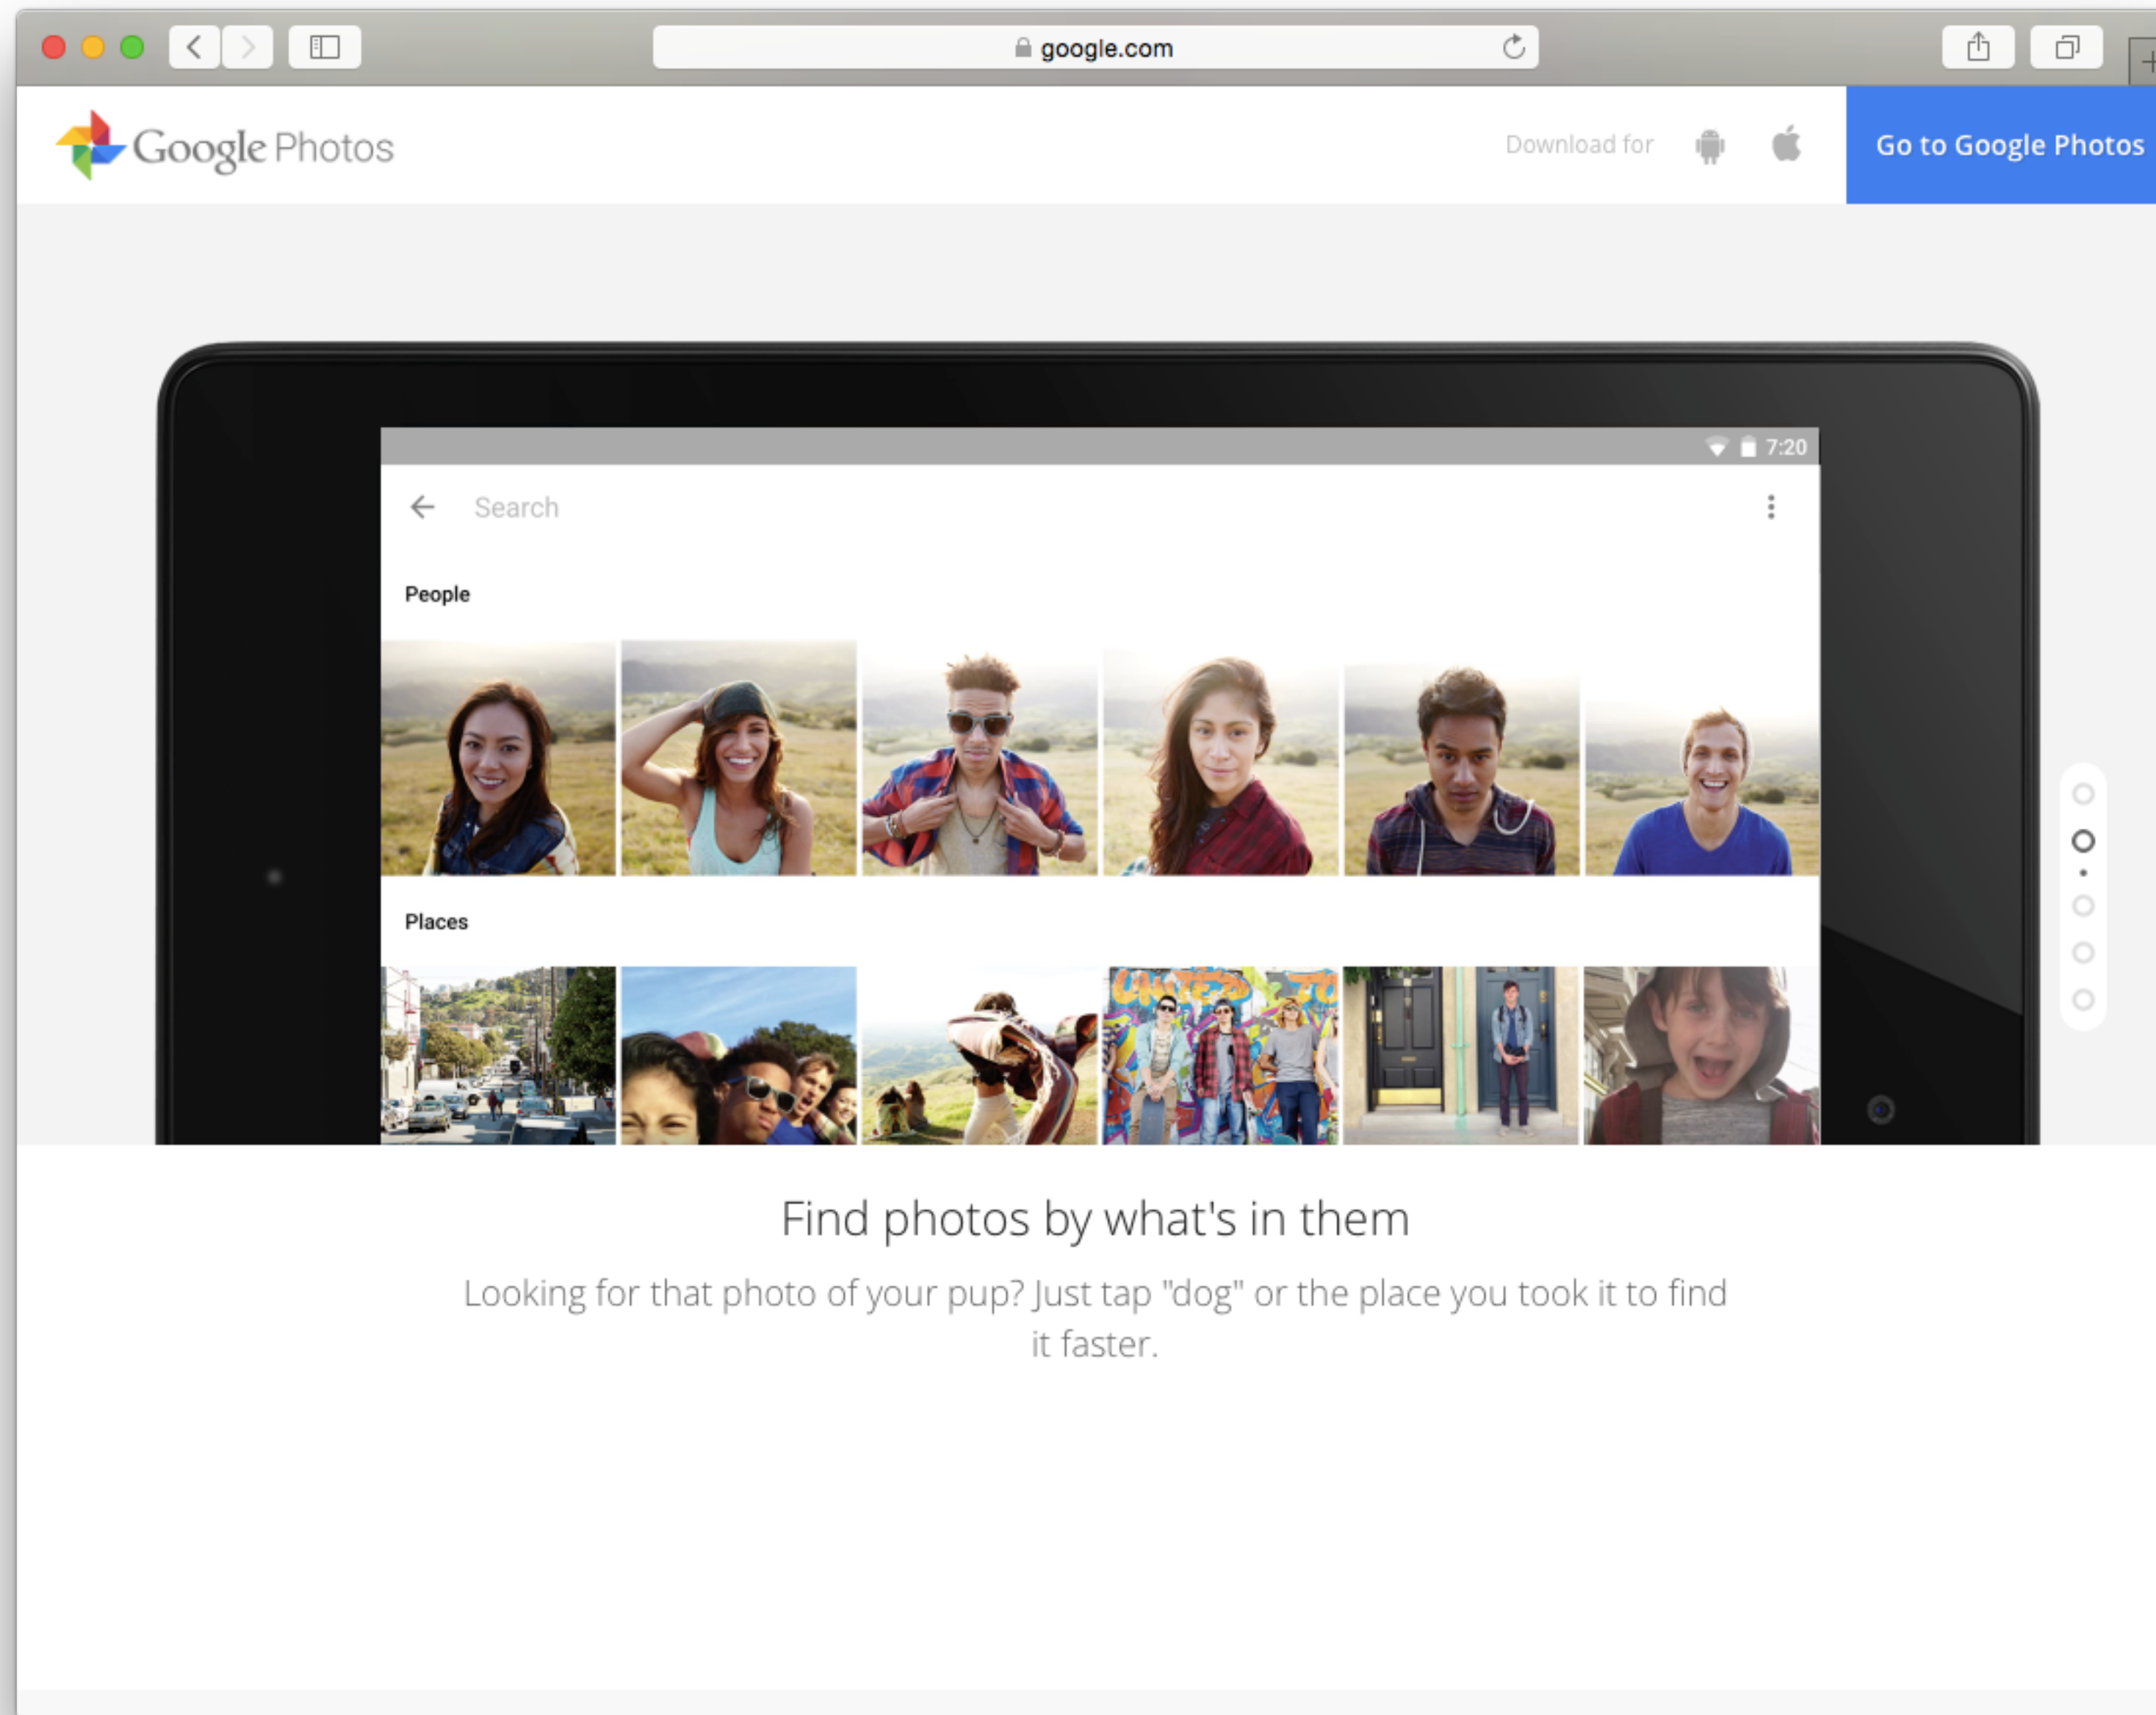

- Learning: improving with experience at some task
 - Improve over **task**
 - with respect to some **performance measure**
 - based on some **experience**
- Writing computer programs that write computer programs

Outline

- Three machine learning stories/cautionary tales
- Deep learning definition
- Types of machine learning
- Best practices

Machine Learning Story 1

Face Detection & Recognition

What Does a Human Face Look Like?

Apple II image from wikipedia.com.
Eyes added digitally.

Apple II image from wikipedia.com.
Eyes added digitally.

if pixel153 > 128 & pixel154 > 128 &
pixel155 > 128 & pixel156 < 64 &
sqrt(pixel157) < 82 &
log(pixel1132 * pixel1133) > 1
then image is a face*

* (not a real face recognition program)

ASA Excellence in Statistical Reporting Award

The formula that killed Wall Street

Wall Street in the mid-1980s turned to the quants – brainy financial engineers – to invent new ways to boost profits. They and their managers, though laziness and greed, built a huge financial bubble on foundations that they did not understand. It was a recipe for disaster. The journalist **Felix Salmon** won the American Statistical Association's Excellence in Statistical Reporting Award for 2010. We reprint his article, first published as the cover story of *Wired* magazine, because it brilliantly conveys complex statistical concepts

A formula in
statistics,
misunderstood
and misused, has
devastated the
global economy

In the years before 2008, it was hardly unthinkable that a math wizard like David X. Li might so soon earn a Nobel Prize. After all, financial economists – even Wall Street quants – have received the prize in economics before, and Li's work on measuring risk has had more impact, more quickly, than previous Nobel Prize-winning contributions to the field. But, though, as dazed bankers, politicians, regulators and investors survey the wreckage of the biggest financial meltdown since the Great Depression, Li is probably thankful he still has a job in finance at all. No wonder his achievement should be dismissed. He took an extraordinarily tough nut – determining correlation, and how seemingly disparate events are related – and cracked it.

$$\Pr[T_A < 1, T_B < 1] = \phi_2(\phi^{-1}(F_A(1)), \phi^{-1}(F_B(1)), \gamma)$$

The formula that killed so many pension plans: David X. Li's Gaussian copula, as first published in 2000. Investors exploited it as a quick – and fatally flawed – way to assess risk.

Probability

Specifically, this is a joint default probability – the likelihood that any two members of the pool (A and B) will both default. It's what investors are looking for, and the rest of the formula provides the answer.

Survival times

The amount of time between now and when A and B can be expected to default. Li took the idea from a concept in actuarial science that charts what happens to someone's life expectancy when their spouse dies.

Equality

A dangerously precise concept, since it leaves no room for error. Clean equations help both quants and their managers forget that the real world contains a surprising amount of uncertainty, fuzziness, and precariousness.

Copula

This couples (hence the Latin term copula) the individual probabilities associated with A and B to come up with a single number. Errors here massively increase the risk of the whole equation blowing up.

Distribution functions

The probabilities of how long A and B are likely to survive. Since these are not certainties, they can be dangerous: Small miscalculations may leave you facing much more risk than the formula indicates.

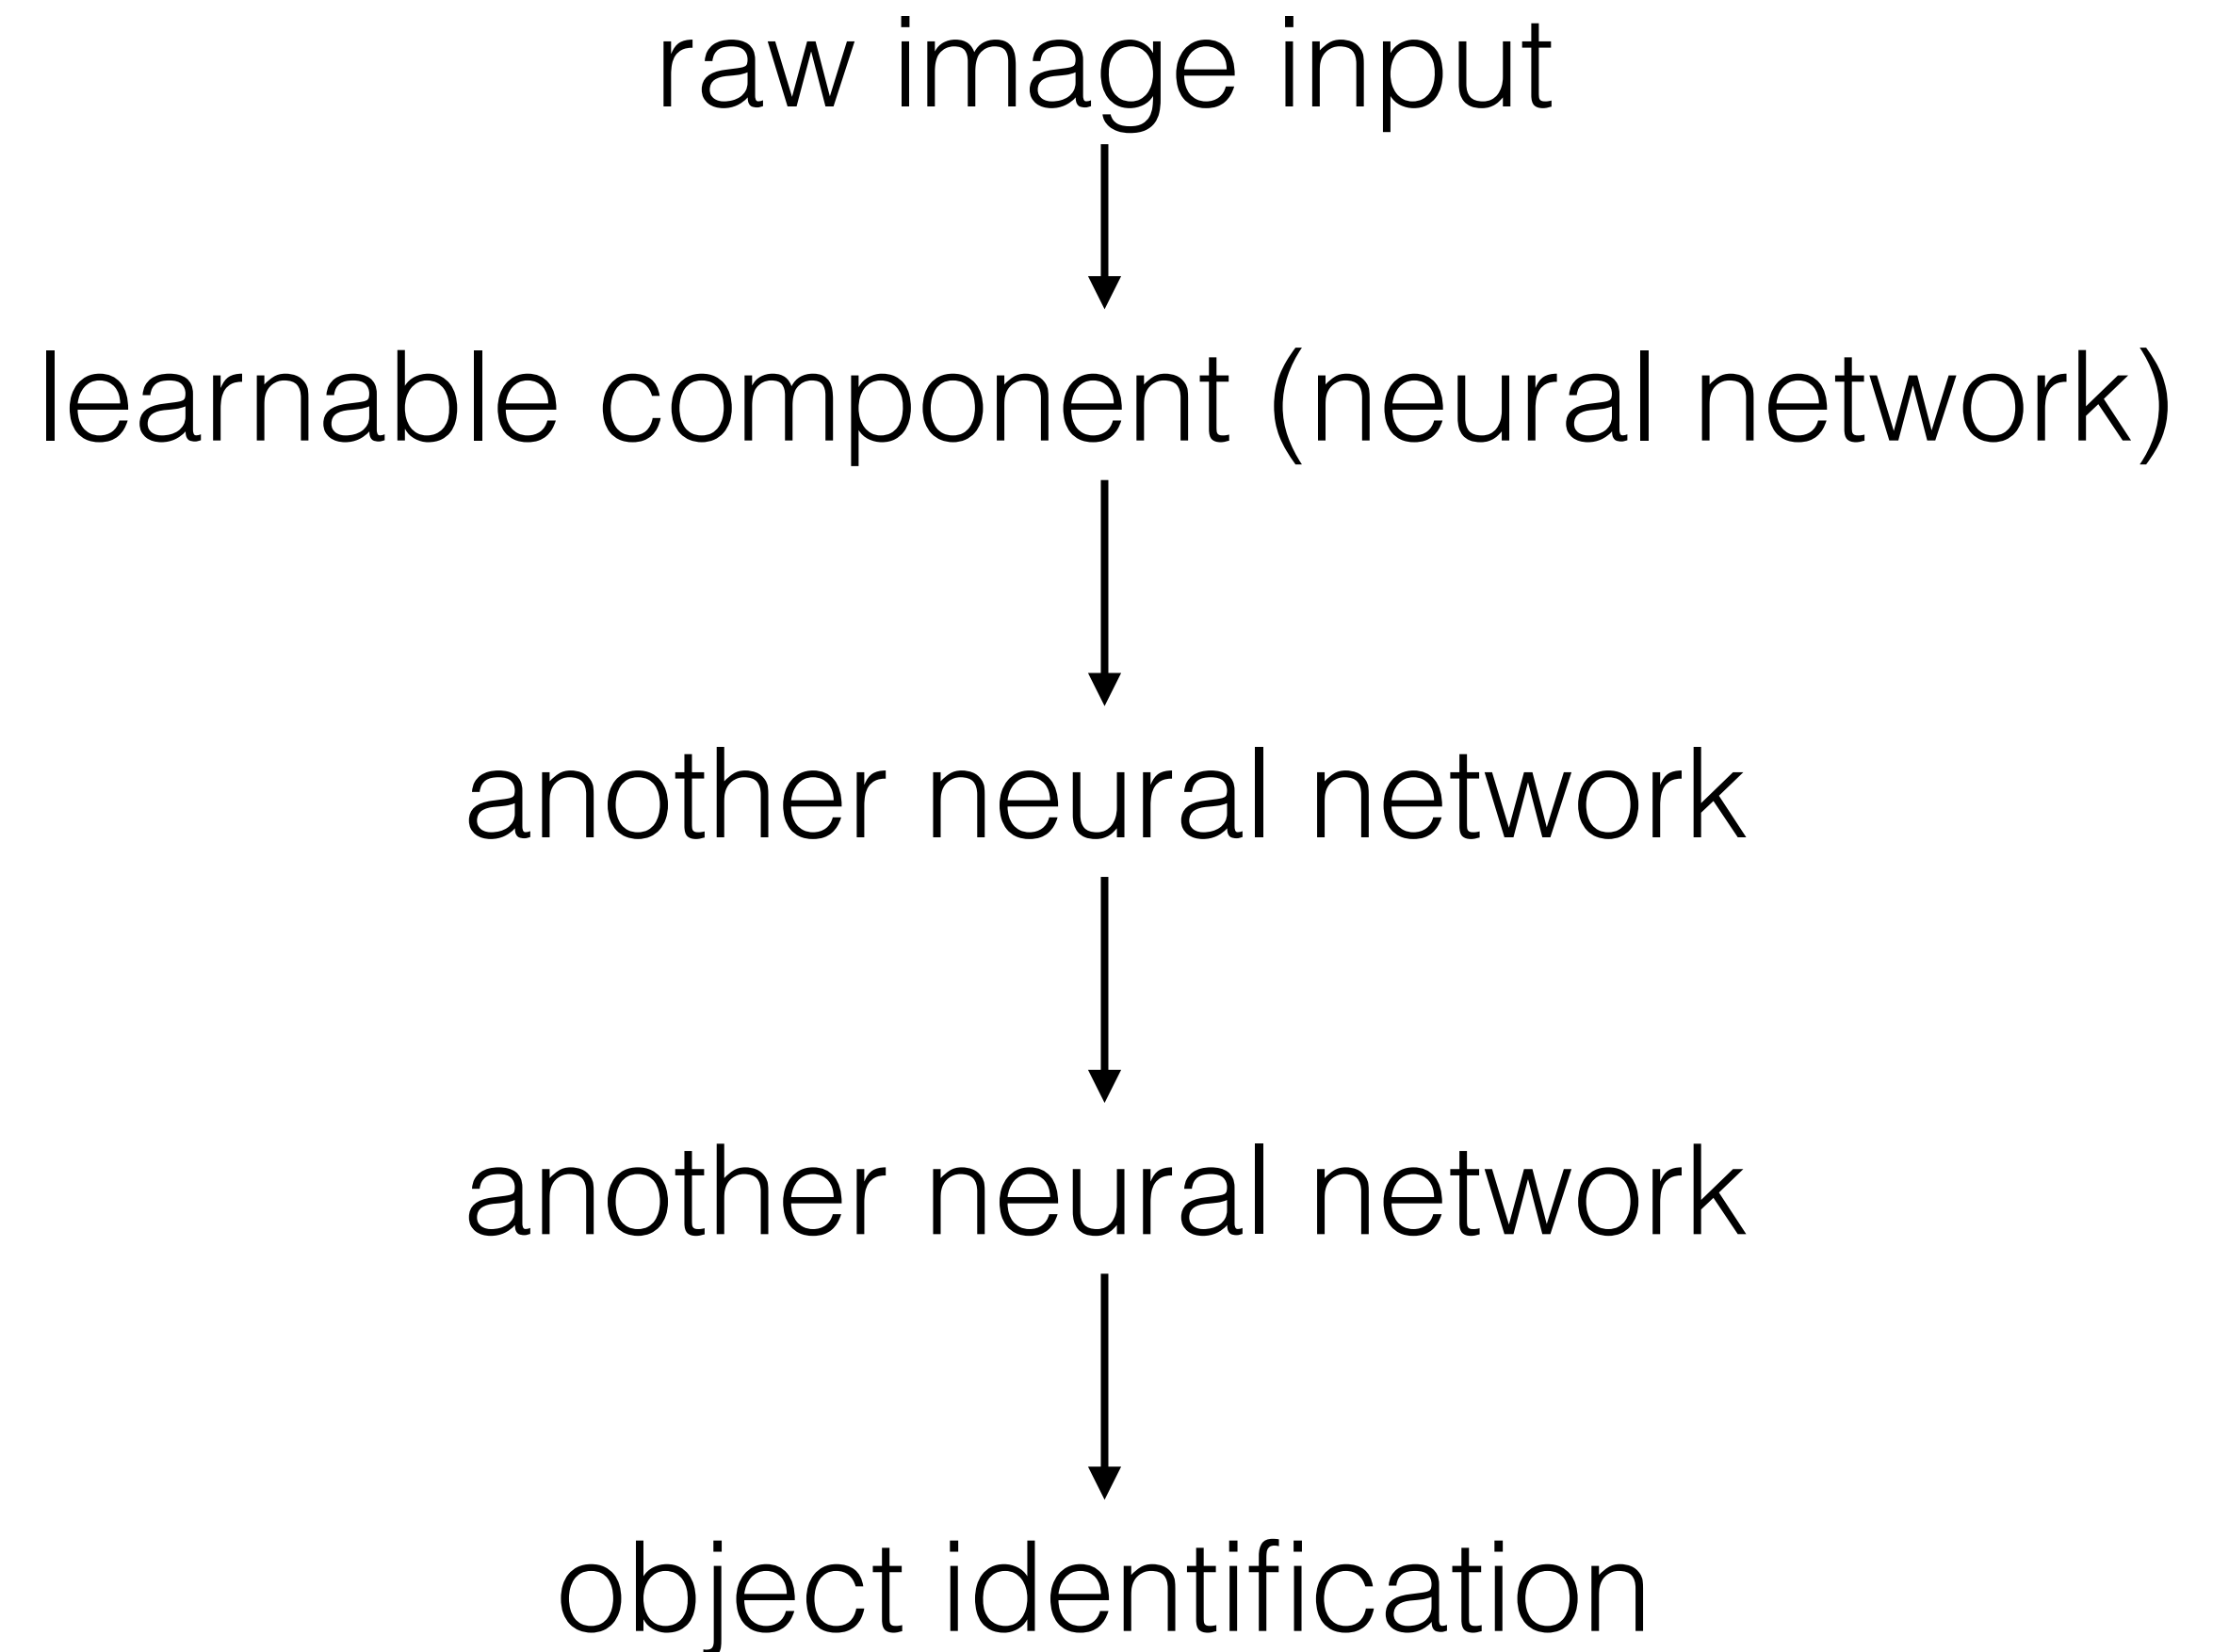

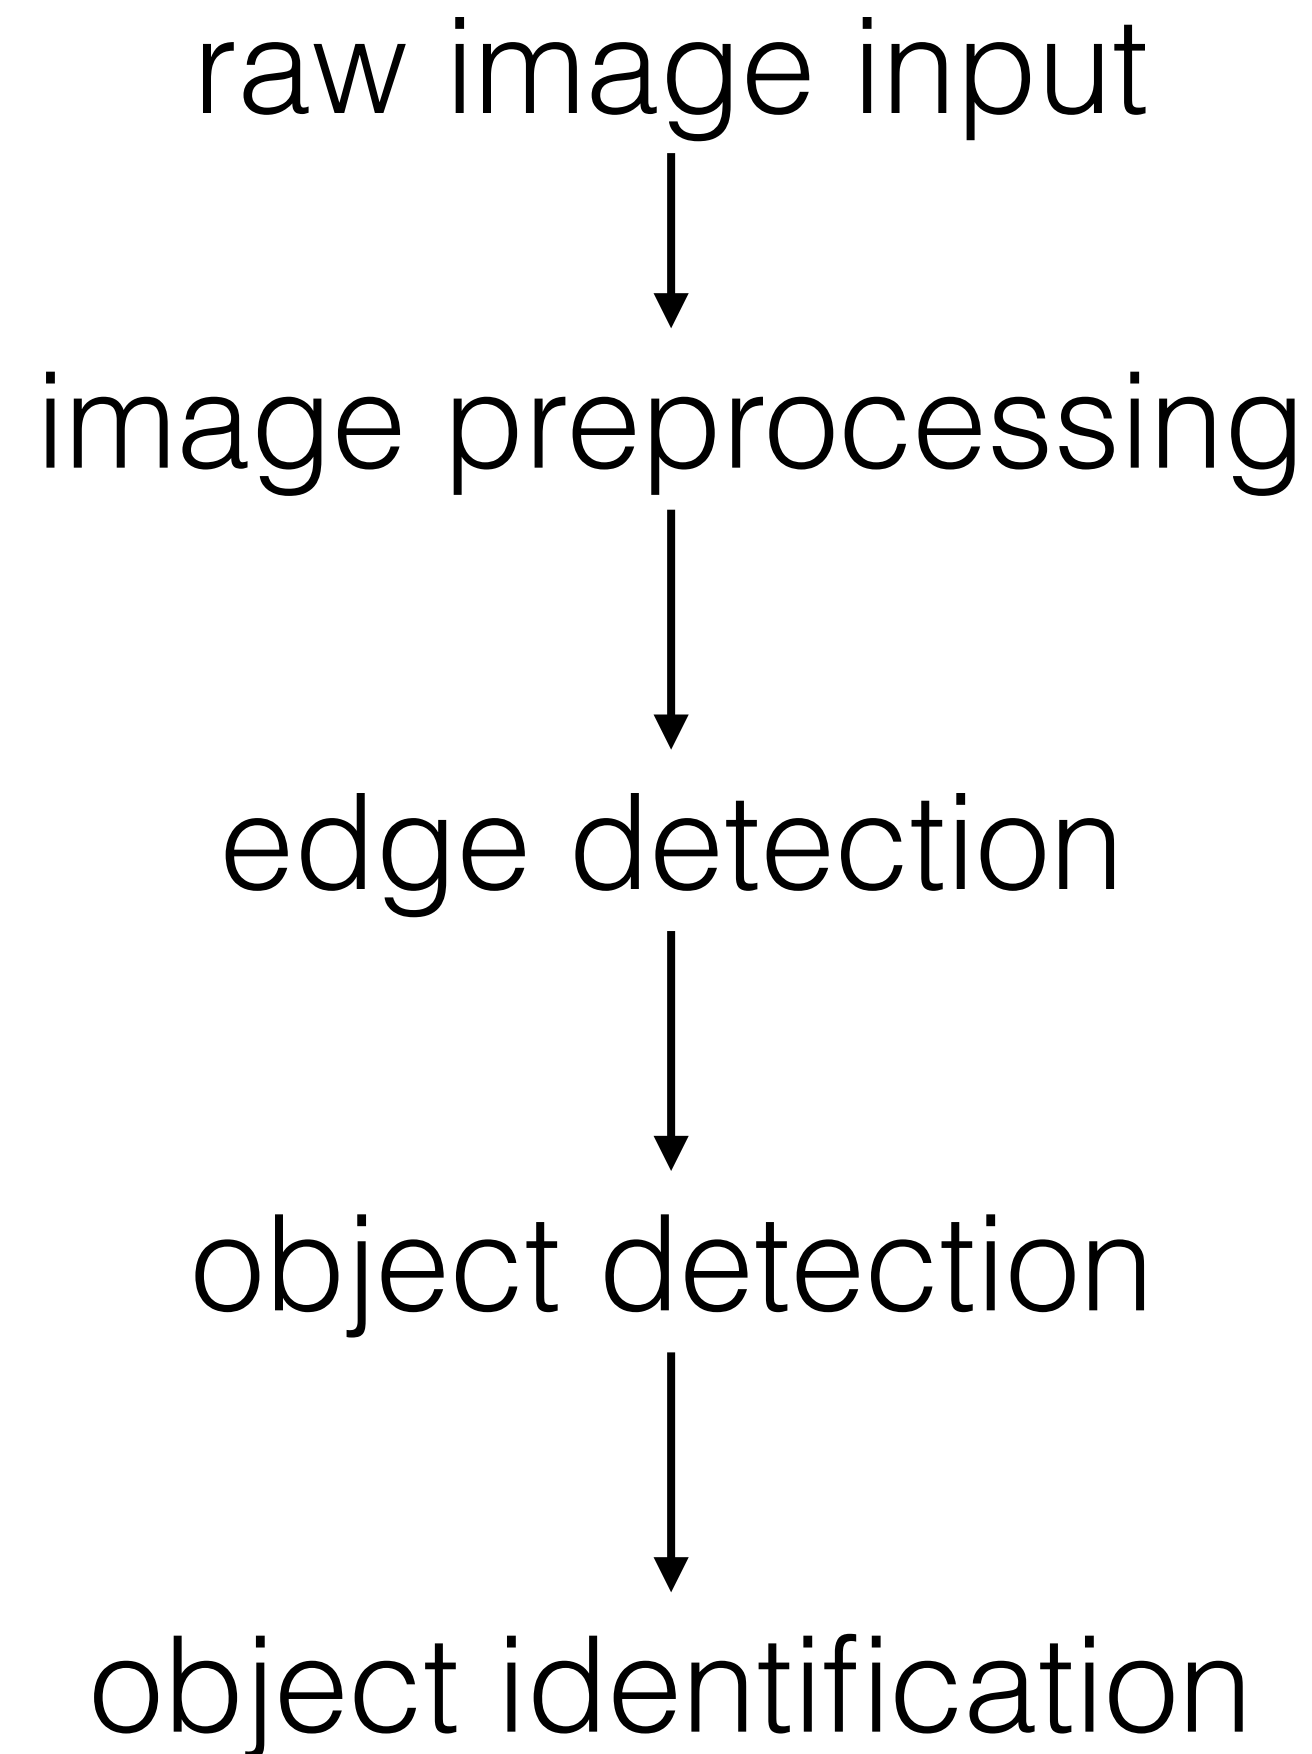

Gamma

The all-powerful correlation parameter, which reduces correlation to a single constant – something that should be highly improbable, if not impossible. This is the magic number that made Li's copula function irresistible.

Machine Learning Stories

- Face recognition
- Recommender systems
- Finance

What is deep learning?

Deep Learning

- Using machine learning to simultaneously train every part of the process from **raw input** to **raw output**
- Considered “deep” when compared to “shallow” approach of training/designing each component on its own

Types of Machine Learning

- Types of learning settings
 - Supervised learning
 - Unsupervised learning
- Types of learning algorithms
 - Batch learning
 - Online learning

Example: Digit Classification

Example: Airline Price Prediction

The screenshot shows the Kayak website interface for a flight search. The search parameters are CLT ↔ HNL, Aug 28 Friday to Aug 28 Friday, Economy cabin, 1 traveler. The search results are sorted by price (low to high), showing 527 of 533 flights. The top result is a \$367 Honolulu Round Trip advertisement. Below that, two flight options are listed, both priced at \$732. The first is a US Airways flight with a 1-stop itinerary (CLT to PHX to HNL, then HNL to CLT). The second is an American Airlines flight with a 1-stop itinerary (CLT to DFW to HNL, then HNL to CLT). The left sidebar contains a price prediction graph, a 'Create a price alert' button, and filters for stops (1 stop selected) and times.

Batch Supervised Learning

- Draw data set $D = \{(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)\}$ from distribution \mathbb{D}
- Algorithm A learns hypothesis $h \in H$ from set H of possible hypotheses $A(D) = h$
- We measure the quality of h as the expected **loss**: $E_{(x,y) \in \mathbb{D}} [\ell(y, h(x))]$
 - This quantity is known as the **risk**
 - E.g., loss could be the Hamming loss $\ell_{\text{Hamming}}(a, b) = \begin{cases} 0 & \text{if } a = b \\ 1 & \text{otherwise} \end{cases}$
classification

Online Supervised Learning

- In step t , draw data point \mathbf{x} from distribution \mathbb{D}
- Current hypothesis h guesses the label of \mathbf{x}
- Get true label from oracle \mathcal{O}
- Pay penalty if $h(\mathbf{x})$ is wrong (or earn reward if correct)
- Learning algorithm updates to new hypothesis based on this experience
 - Does not store history

Learning Settings

- Supervised or unsupervised (or semi-supervised, weakly supervised, transductive...)
- Online or batch (or reinforcement...)
- Classification, regression
 - (or structured output, clustering, dimensionality reduction...)

Best Practices

- Try range of models with different **capacity**
- Split data into training, validation, and testing sets
- Measure performance on evaluation set to tune parameters
- Measure performance on testing set as final check

Held-out Validation

0	0	0	0	0
1	1	1	1	1
2	2	2	2	2
