TAME

Event Based Concurrency System

What is TAME?

- Event based concurrency system
 - **C++ libraries and source-to-source translation**
 - **For network applications**
 - **No “stack-ripping”**
 - **Type safe (templates)**
 - **Performance of events**
 - **Programmability of threads**

Events Vs. Threads

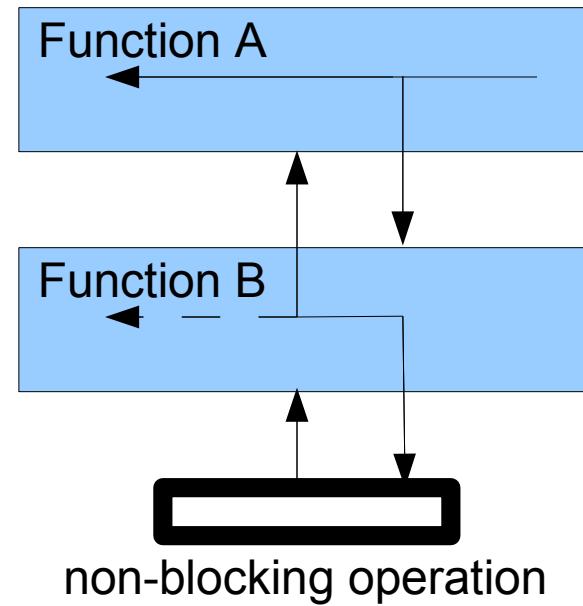

Measure	Threads	Events
Support for extremely high concurrency	X	√
Portability	X	√
Better performance, Less use of memory	X	√
No stack-ripping	X	√

Events Vs. Threads

Threads

Events

Semantics Example

```
// Threads
void wait_then_print_threads() {
sleep(10); // blocks this function and all callers
printf("Done!");
}
```

```
// Tame primitives
tamed wait_then_print_tame() {
tvars { rendezvous<> r; }
event<> e = mkevent(r); // allocate event on r
timer(10, e); // cause e to be triggered after 10 sec
twait(r); // block until an event on r is triggered
// only blocks this function, not its callers!
printf("Done!");
}
```

```
// Tame syntactic sugar
tamed wait_then_print_simple_tame() {
twait { timer(10, mkevent()); }
printf("Done!");
}
```

TAME Primitives

Classes	Keywords & Language Extensions	Functions & Methods
<p>event<></p> <ul style="list-style-type: none"> • A basic event. <p>event<<i>T</i>></p> <ul style="list-style-type: none"> • An event with a single <i>trigger value</i> of type <i>T</i>. This value is set when the event occurs; an example might be a character read from a file descriptor. Events may also have multiple trigger values of types $T_1 \dots T_n$. <p>rendezvous<<i>I</i>></p> <ul style="list-style-type: none"> • Represents a set of outstanding events with event IDs of type <i>I</i>. Callers name a rendezvous when they block, and unblock on the triggering of any associated event. 	<p>twait(<i>r</i>[, <i>i</i>]);</p> <ul style="list-style-type: none"> • A wait point. Block on explicit rendezvous <i>r</i>, and optionally set the event ID <i>i</i> when control resumes. <p>tamed</p> <ul style="list-style-type: none"> • A return type for functions that use twait. <p>tvars { ... }</p> <ul style="list-style-type: none"> • Marks safe local variables. <p>twait { <i>statements</i>; }</p> <ul style="list-style-type: none"> • Wait point syntactic sugar: block on an implicit rendezvous until all events created in <i>statements</i> have triggered. 	<p>mkevent(<i>r</i>, <i>i</i>, <i>s</i>);</p> <ul style="list-style-type: none"> • Allocate a new event with event ID <i>i</i>. When triggered, it will awake rendezvous <i>r</i> and store trigger value in slot <i>s</i>. <p>mkevent(<i>s</i>);</p> <ul style="list-style-type: none"> • Allocate a new event for an implicit twait{} rendezvous. When triggered, store trigger value in slot <i>s</i>. <p><i>e</i>.trigger(<i>v</i>);</p> <ul style="list-style-type: none"> • Trigger event <i>e</i>, with trigger value <i>v</i>. <p>timer(<i>to</i>, <i>e</i>); wait_on_fd(<i>fd</i>, <i>rw</i>, <i>e</i>);</p> <ul style="list-style-type: none"> • Primitive event interface for timeouts and file descriptor events, respectively.

Figure 2: Tame primitives for event programming in C++.

Wait Points

- blocks calling function until 1+ events triggered
- function returns to its caller
- but the function does not complete
- execution point and local vars are preserved
- When an event occurs, the function “unblocks” and resumes processing at the wait point

```
twait { statements; }
```

```
{ rendezvous<> __r;  
statements; // where mkevent calls create events on __r  
while (not all __r events have completed)  
twait(__r); }
```

Safe Local Variables

- Their values are preserved across wait points
- Preserved in a heap-allocated closure
- `tvars {}`
- Unsafe local variables have indeterminate values after a wait point
- Compile warnings when a local variable should be made safe

Closures

- Internally, Tame writes a new C++ structure for each tamed function
- Each tamed function has one closure, contains:
 - **Next statement to execute**
 - **Function parameters**
 - **tvars variables**
 - **rendezvous**

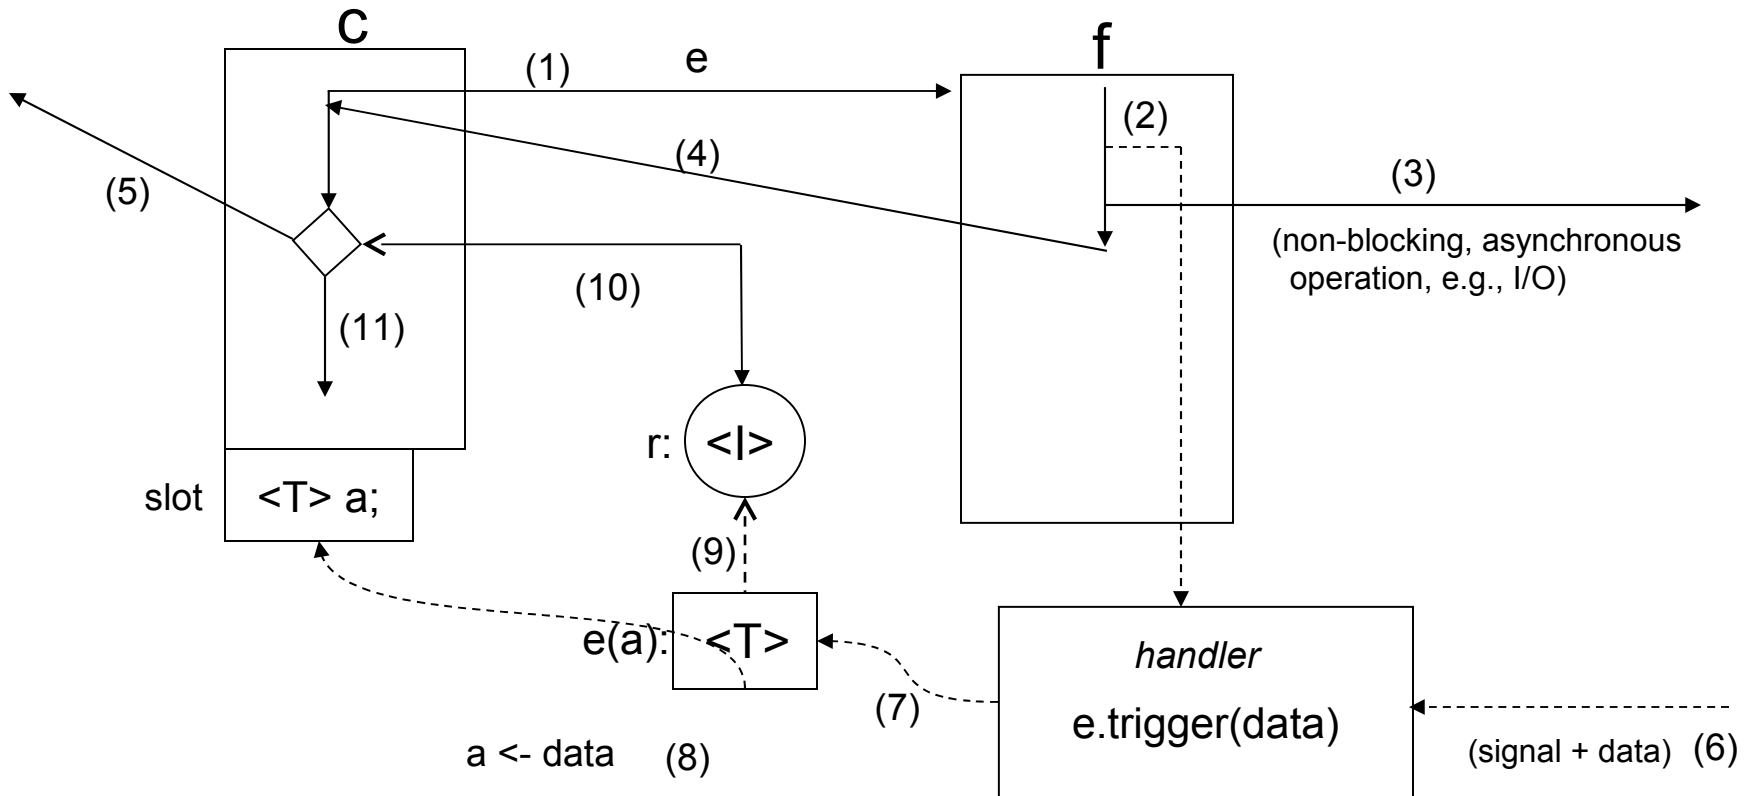

Closures Translation

```
tamed A::f(int x) {  
  tvars { rendezvous<> r; }  
  a(mkevent(r)); twait(r); b(); }
```

```
void A::f(int __tame_x, A_f_closure *__cls) {  
  if (__cls == 0)  
    __cls = new A_f_closure(this, &A::fn, __tame_x);  
  assert(this == __cls->this_A);  
  int &x = __cls->x;  
  rendezvous<> &r = __cls->r;  
  switch (__cls->entry_point) {  
  case 0: // original entry  
    goto __A_f_entry_0;  
  case 1: // reentry after first twait  
    goto __A_f_entry_1; }  
  __A_f_entry_0:  
  a(_mkevent(__cls,r));  
  if (!r.has_queued_trigger()) {  
    __cls->entry_point = 1;  
    r.set_reenter_closure(__cls);  
    return; }  
  __A_f_entry_1:  
  b();  
}
```

A “Tame” solution

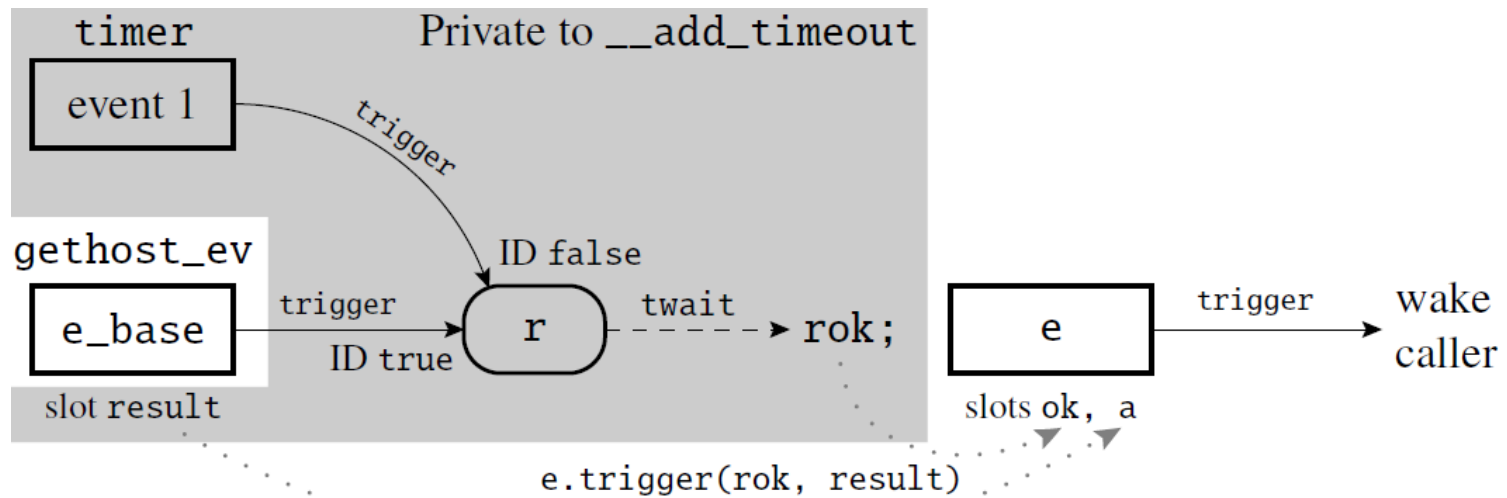

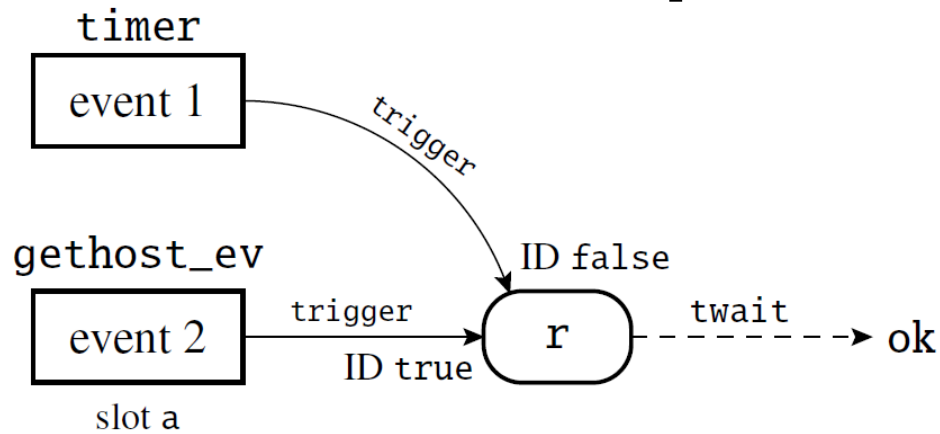

◇ wait point

○ <|> rendezvous<|>

□ <T> event<T>

Composeability

Memory Management

```
tamed broken(dnsname nm) {
  tvars { rendezvous<> r; ipaddr res; }
  gethost_ev(nm, mkevent(r, res));
  // Whoops: forgot to twait(r)!
}
```

■ Solution is reference-counting

- **Keep track of events and closures**
- **C++ “smart pointer” classes**

■ Two types of reference counts

- **Strong references**
 - are conventional reference counts
- **Weak references**
 - Allow access to the object only if not deallocated

(a) After the event allocation on line 3.

(b) After control exits broken on line 5.
