

Chapter 2

Using the Operating system

Resource Descriptors

- ✍ The OS implements Abstraction of each of this
 - ✍ Unit of Computation is a 'process'
 - ✍ Unit of information storage is a 'file'
- ✍ For each resource abstraction (file, memory, processor), OS maintains a resource descriptor
- ✍ Resource descriptor:
 - ✍ Identify resources
 - ✍ Current state
 - ✍ What process it is associated with, if it is allocated
 - ✍ Number and identity of available units

Resource Descriptors...

✍ File descriptor:

- ✍ File name
- ✍ File type (Sequential, Indexed, ...)
- ✍ Owner
- ✍ State (Open, Closed)
- ✍ Extents (mapping to the physical storage)

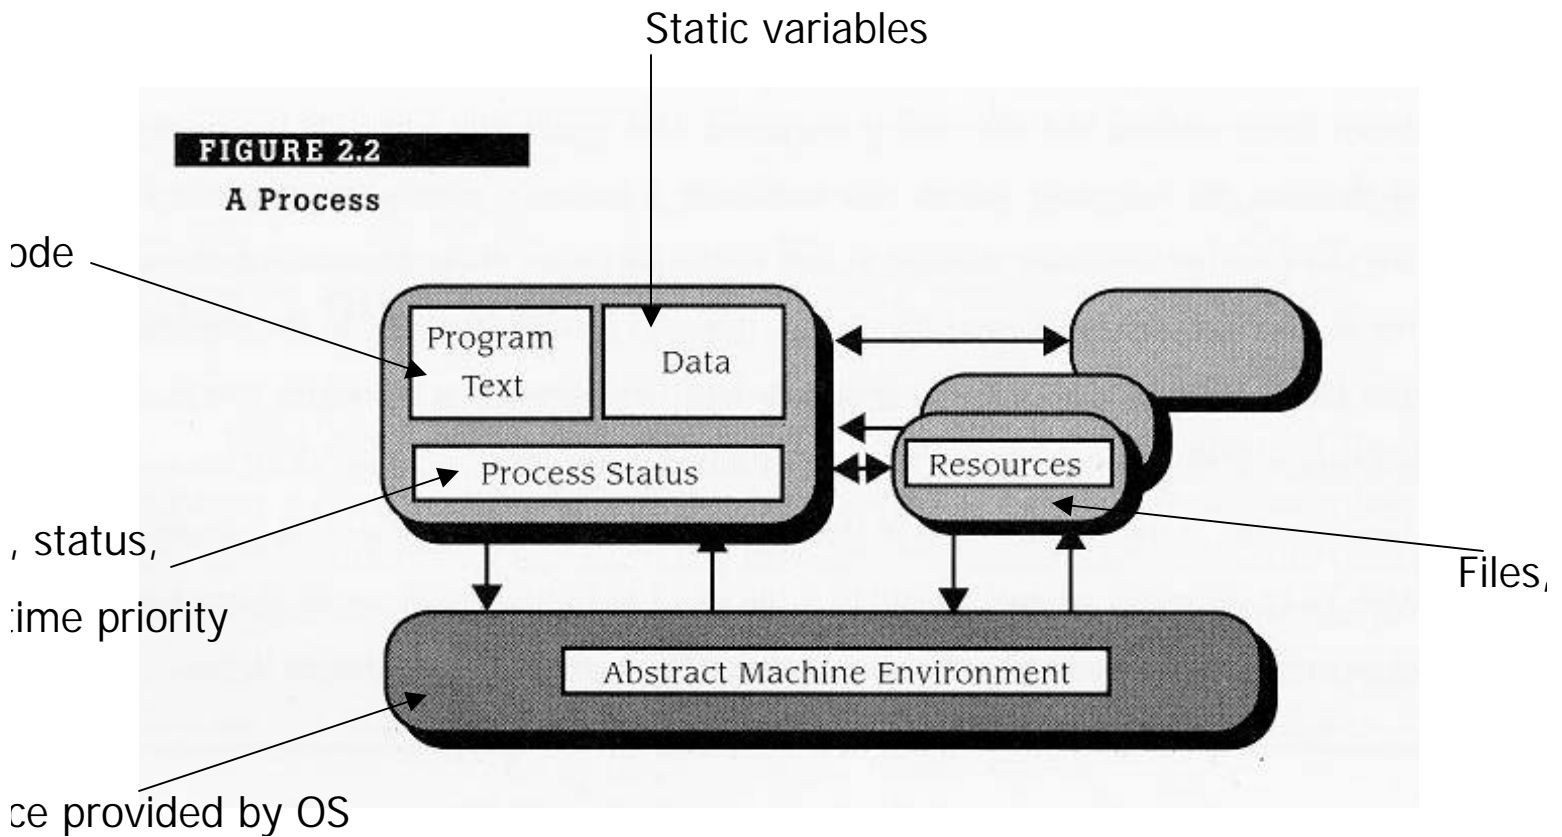

✍ Process descriptor

- ✍ Object program (Program text)
- ✍ Data segment
- ✍ Process Status Word (PSW) – executing, waiting, ready
- ✍ Resources acquired

Process & Process Descriptor

Contents of a descriptor maps directly to the Abstract Machine provided by the OS

FIGURE 2.2
A Process

One Program / Multiple Instantiations

FIGURE 2.3
Sequential Operation

Note:

Each Process has **own** descriptor - text (shared), c

Only **one** process active at a time (context switchin

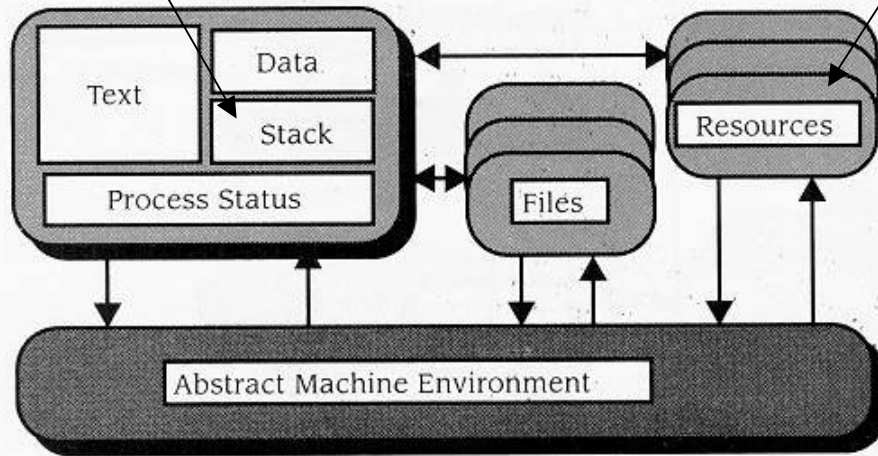

Process

- ✍ 3 units of computations:
 - ✍ Process
 - ✍ Thread
 - ✍ Object
- ✍ Process: 'heavy-weight' process
 - ✍ OS overhead to **create and maintain descriptor** is expensive
- ✍ Thread: "light-weight" process
 - ✍ OS maintains minimal internal state information
- ✍ Objects: 'heavy-weight' process
 - ✍ Instantiation of a class

UNIX Processes

- Dynamically allocated variables
- Runtime stack

FIGURE 2.4
UNIX Processes

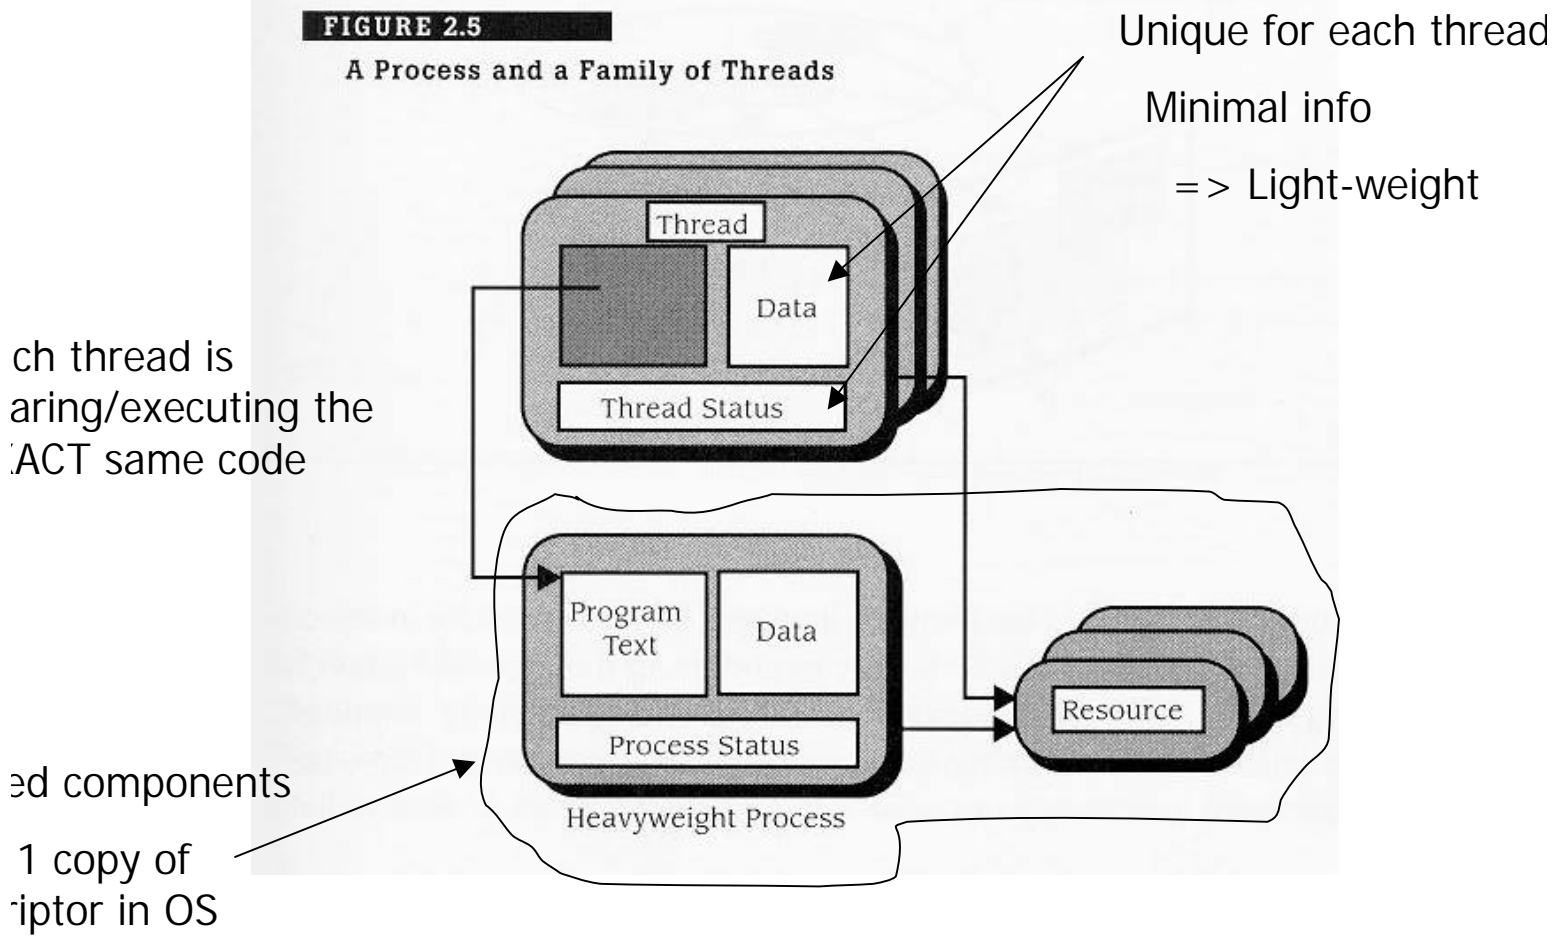

Thread

- ✍ Thread: light-weight process
 - ✍ OS maintains minimal internal state information
- ✍ Usually instantiated from a process
- ✍ Each thread has its OWN unique descriptor
 - ✍ Data, Thread Status Word (TSW)
- ✍ SHARES with the parent process (and other threads)
 - ✍ Program text
 - ✍ Resources
 - ✍ Parent process data segment

Thread ...

FIGURE 2.5

A Process and a Family of Threads

Threads... example

FIGURE 2.6
Using Threads

Multiple lightweight processes; one resource allocated

=> Only one physical resource has to be maintained by OS

=> Less OS overhead, better response

Threads share access to physical screen

- Screen resource allocated to heavyweight process

Objects

✍ Objects:

- ✍ Derived from SIMULA '67
- ✍ Defined by classes
- ✍ Autonomous

✍ Classes

- ✍ Abstract Data Types (ADT)
- ✍ Private variables

✍ An instantiation of a class is an Object

Objects

- ✍ Objects are heavy-weight processes
 - ✍ have full descriptors
- ✍ Object communicate via Message passing
- ✍ OOP:
 - ✍ Appeals to intuition
 - ✍ Only recently viable
 - ✍ Overhead of instantiation and communication

Computational Environment

- ✍ When OS is started up
 - ✍ Machine abstraction created
 - ✍ Hides hardware from User and Application
 - ✍ Instantiates processes that serve as the user interface or “Shell”
 - ✍ Shell (UI) instantiates user processes

- ✍ Consider UNIX:

UNIX \Longrightarrow getty \Longrightarrow shell \Longrightarrow user process

- ✍ What are the advantages & disadvantages of so many processes just to execute a program ?

Advantages & Disadvantages

✍ Advantages...

Each process (UNIX, getty, shell, ...) has its own 'protected' execution environment

✍ If child process fails from fatal errors, no (minimal) impact on parent process

✍ Disadvantages...

OS overhead in

✍ Maintaining process status

✍ Context switching

Process Creation – UNIX fork()

- ✍ Creates a child process that is a '**Thread**'
- ✍ Child process is duplicate (initially) of the parent process – except for the process id
- ✍ Shares access to all resources allocated at the time of instantiation and Text
- ✍ Has duplicate copy of data space BUT is its own copy and it modify only its own copy

If a child Process requests / receives a resource, does the parent or other children have access to it ?

Process creation - fork()... example

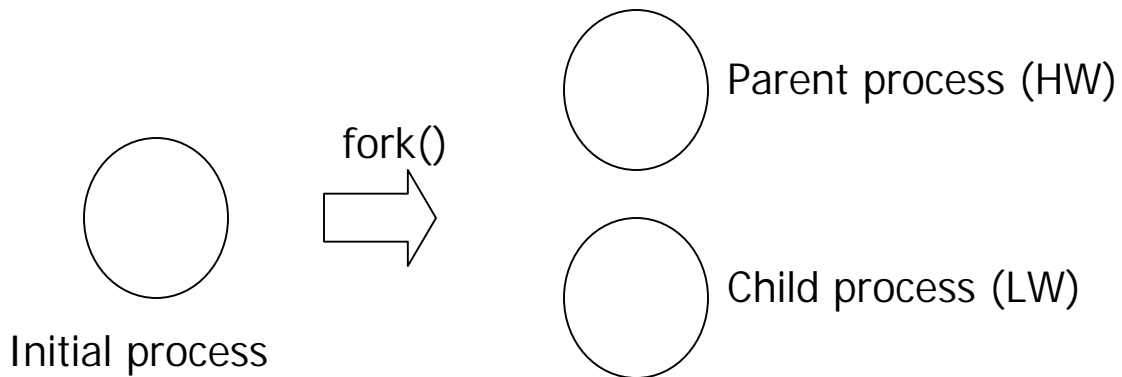

```
int pidValue;
..
pidValue = fork();           /* creates a child process
If(pidValue == 0) {
    /* pidValue is ZERO for child, nonzero for parent
    /* The child executes this code concurrently with Parent
    childsPlay(..);         /* A locally-liked procedure
    exit(0);                /* Terminate the child
}
/* The Parent executes this code concurrently with the child
..
wait(..);                   /* Parent waits for Child's to terminate
```

UNIX process creation : fork() facility

Fall 1999 : CS 3204 - Arthur

Process creation – Unix fork()...

- Child/Parent code executed based on the pid value in “local” data space
 - For parent process, pid value returned is that of the *child* (non-zero)
 - For child process, pid value returned is 0
- pidvalue returned to parent process is non-Zero
- Therefore, fork() creates a new LW process

Process Creation – Unix exec()

- ✍ Turns LW process into autonomous HW process
- ✍ fork()
 - ✍ Creates new process
- ✍ exec()
 - ✍ Brings in new program to be executed by that process
 - ✍ New text, data, stack, resources, PSW, etc.
BUT using same (expanded) process descriptor entries

In effect, the “exec’ed” code overlays “exec’ing” code

Process creation – exec()... example

```
int pid;
..
    /* Setup the argv array for the child    */
..
if((pid = fork()) == 0) {           /* Create a child
    /* The child process executes changes to its own program
execve( new_program.out , argv , 0 );
    /*Only return from an execve call if it fails
    printf("Error in execve");
    exit(0);                        /* Terminate the child
}
    /* Parent executes this code    */
..
wait(..);                          /* Parent waits for Child's to terminate
```

UNIX process creation: exec() facility
