

### Memory Management

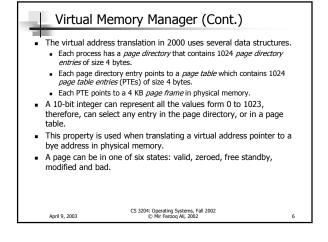

- Sophisticated virtual memory (VM) management
  - Assumption is that underlying hardware supports virtual-to-physical address translation, paging, and other VM features
- The VM manager in 2000 uses a page-based management scheme with a page size of 4 KB
- VM manager uses 32 bit addresses, so each process has a 4 GB virtual address space
  - Upper 2 GB are identical for each process and lower 2 GB are distinct for each process
- Two-step memory allocation procedure
  - 1. Reservation a portion of the process' address space
  - Commitment of the allocation by assigning space in the OS paging file

# Programmer Interface - Memory Management ■ Virtual memory: - VirtualAlloc reserves or commits virtual memory. - VirtualFree decommits or releases the memory. ■ These functions enable the application to determine the virtual address at which the memory is allocated. ■ An application can use memory by memory mapping a file into its address space. ■ Multistage process. ■ Two processes share memory by mapping the same file into their virtual memory. ## Linux Memory Management

- Linux's physical memory-management system deals with allocating and freeing pages, groups of pages, and small blocks of memory.
- It has additional mechanisms for handling virtual memory, memory mapped into the address space of running processes.

### Managing Physical Memory

- The page allocator allocates and frees all physical pages; it can allocate ranges of physically-contiguous pages on request.
- The allocator uses a buddy-heap algorithm to keep track of available physical pages.
  - Each allocatable memory region is paired with an adjacent partner.
  - Whenever two allocated partner regions are both freed up they are combined to form a larger region.
  - are combined to form a larger region.

    If a small memory request cannot be satisfied by allocating an existing small free region, then a larger free region will be subdivided into two partners to satisfy the request.
- Memory allocations in the Linux kernel occur either statically (drivers reserve a contiguous area of memory during system boot time) or dynamically (via the page allocator).

# Virtual Memory

- The VM system maintains the address space visible to each process: It creates pages of virtual memory on demand, and manages the loading of those pages from disk or their swapping back out to disk as required.
- The VM manager maintains two separate views of a process's address space:
  - A logical view describing instructions concerning the layout of the address space.
  - The address space consists of a set of nonoverlapping regions, each representing a continuous, page-aligned subset of the address space.
  - A physical view of each address space which is stored in the hardware page tables for the process.

### Virtual Memory (Cont.)

- Virtual memory regions are characterized by:
  - The backing store, which describes from where the pages for a region come; regions are usually backed by a file or by nothing (demand-zero memory)
  - The region's reaction to writes (page sharing or copy-on-write).
  - The kernel creates a new virtual address space
    - 1. When a process runs a new program with the **exec** system call
    - 2. Upon creation of a new process by the **fork** system call

19

### Virtual Memory (Cont.)

- On executing a new program, the process is given a new, completely empty virtual-address space; the program-loading routines populate the address space with virtual-memory regions.
  - Creating a new process with fork involves creating a complete copy of the existing process's virtual address space.
    - The kernel copies the parent process's VMA descriptors, then creates a new set of page tables for the child.
    - The parent's page tables are copied directly into the child's, with the reference count of each page covered being incremented.
    - After the fork, the parent and child share the same physical pages of memory in their address spaces.

### Virtual Memory (Cont.)

- The VM paging system relocates pages of memory from physical memory out to disk when the memory is needed for something else.
- The VM paging system can be divided into two sections:
  - The pageout-policy algorithm decides which pages to write out to disk, and when.
  - The paging mechanism actually carries out the transfer, and pages data back into physical memory as needed.

- The Linux kernel reserves a constant, architecturedependent region of the virtual address space of every process for its own internal use.
- This kernel virtual-memory area contains two regions:
  - A static area that contains page table references to every available physical page of memory in the system, so that there is a simple translation from physical to virtual addresses when running kernel code.
  - The reminder of the reserved section is not reserved for any specific purpose; its page-table entries can be modified to point to any other areas of memory.

### **Executing and Loading User Programs**

- Linux maintains a table of functions for loading programs; it gives each function the opportunity to try loading the given file when an exec system call is made.
  - The registration of multiple loader routines allows Linux to support both the ELF and a.out binary formats.
  - Initially, binary-file pages are mapped into virtual memory; only when a program tries to access a given page will a page fault result in that page being loaded into physical memory.
  - An ELF-format binary file consists of a header followed by several page-aligned sections; the ELF loader works by reading the header and mapping the sections of the file into separate regions of virtual memory.

### Static and Dynamic Linking

- A program whose necessary library functions are embedded directly in the program's executable binary file is *statically* linked to its libraries.
  - The main disadvantage of static linkage is that every program generated must contain copies of exactly the same common system library functions.
  - *Dynamic* linking is more efficient in terms of both physical memory and disk-space usage because it loads the system libraries into memory only once.
