

## Chapter 6

# Process Management

## OS organization

Fall 1999 : CS 3204 - Arthur

2

## Process Management Tasks

- Define & implement the essential characteristics of a process and thread
  - Algorithms to define the behavior
  - Data structures to preserve the state of the execution
- Define what "things" threads in the process can reference – the *address space* (most of the "things" are memory locations)
- Manage the resources used by the processes/threads
- Tools to create/destroy/manipulate processes & threads

Fall 1999 : CS 3204 - Arthur

3

## Process management (...ctd)

- Tools to time-multiplex the CPU – Scheduling the (Chapter 7)
- Tools to allow threads to synchronize the operation with one another (Chapters 8-9)
- Mechanisms to handle deadlock (Chapter 10)

Fall 1999 : CS 3204 - Arthur

4

## Introduction

- Scenario
  - One process running
  - One/more process performing I/O
  - One/more process waiting on resources
- Most of the complexity stems from the need to manage multiple processes

Fall 1999 : CS 3204 - Arthur

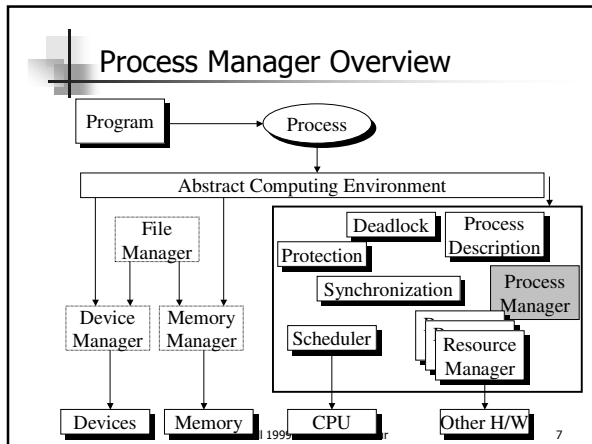

5

## Introduction

- Process Manager
  - CPU sharing
  - Process synchronization
  - Deadlock prevention

Fall 1999 : CS 3204 - Arthur

6

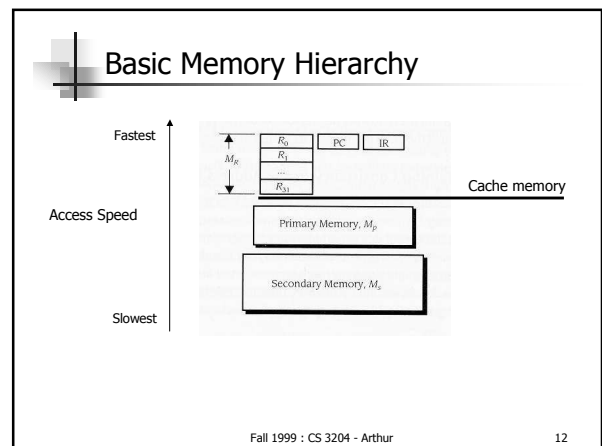

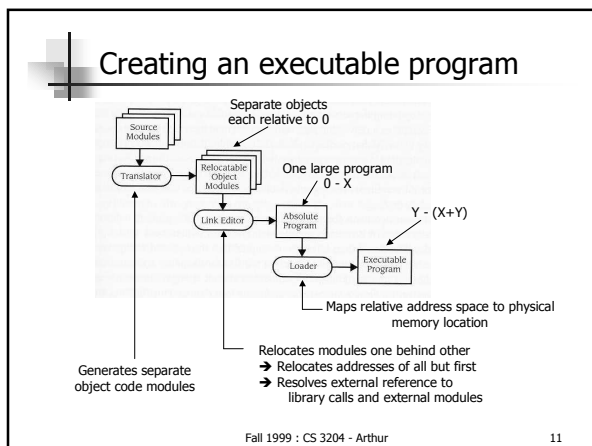

- ### Process components
- Program
    - defines behavior
  - Data
  - Resources
  - Process Descriptor
    - keeps track of process during execution

### Process Descriptor

FIELD	DESCRIPTION
Internal process name	An internal name of the process, such as an integer or table index, used in the operating system code.
State	The process's current state.
Owner	A process has an owner (identified by the owner's internal identification such as the login name). The descriptor contains a field for storing the owner identification.
Parent process descriptor	A pointer to the process descriptor of this process's parent.
List of child process descriptors	A pointer to a list of the child processes of this process.
List of reusable resources	A pointer to a list of reusable resource types held by the process. Each resource type will be a descriptor of the number of units of the resource.
List of consumable resources	Similar to the reusable resource list (see Section 6.3.2).
List of file descriptors	A special case of the reusable resource list.
Message queue	A special case of the consumable resource list.
Protection domain	A description of the access rights currently held by the process (see Chapter 14).
CPU status register content	A copy of each of the CPU status registers at the last time the process exited the running state.
CPU general register content	A copy of each of the CPU general registers at the last time the process exited the running state.

- ### Process Address Space
- Defines all aspects of process computation
    - Program
    - Variables
    - ...
  - Address space is generated/defined by translation

## Basic Memory Hierarchy...

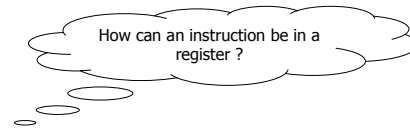

- At any point in the same program, element can be in
  - Secondary memory  $M_S$
  - Primary memory  $M_P$
  - Registers  $M_R$
- Consistency is a Problem
  - $M_S \neq M_P \neq M_R$  (code vs data)
  - When does one make them consistent?
  - How?

Fall 1999 : CS 3204 - Arthur

13

## Consistency Problem

- Scheduler switching out processes – Context Switch
- Is Instruction a Problem ???
  - NO
  - Instructions are never modified
  - Separate Instruction and Data space
  - Therefore,  $M_{R_i} = M_{P_i} = M_{S_i}$

Fall 1999 : CS 3204 - Arthur

14

## Consistency Problem...

- Is Data a Problem ???
  - YES
  - Variable temporarily stored in register has value added to it
  - Therefore,  $M_{R_j} \neq M_{P_j}$
- On context switch, all registers are saved
  - Therefore, current state is saved

Fall 1999 : CS 3204 - Arthur

15

## Sample Scenario...

- Suppose 'MOV X Y' instruction is executed
  - $\rightarrow M_{P_y} \neq M_{S_y}$
- On context switch, is all of a process' memory flushed to  $M_S$ ?
  - No, only on page swap
- Hence,  $env_{process} = (M_R + M_S) + (...)$
- Note:
  - Flushing of memory frees it up for incoming process  
 $\Rightarrow$  Page Swap

Fall 1999 : CS 3204 - Arthur

16

## Process States

- Focus on Resource Management & Process Management

- Recall also that part of the process environment is its **state**

State Transition Diagram

Fall 1999 : CS 3204 - Arthur

17

## Process States...

- When process enters 'Ready' state, it must compete for CPU. Memory has already been allocated
- Process has CPU
- Process requests resource that is immediately available  $\rightarrow$  NO blocking
- Process requests resource that is NOT yet available
- Resource allocated, memory re-allocated?

State Transition Diagram

Fall 1999 : CS 3204 - Arthur

18

## Resources & Resource Manager

- 2 types of Resources
  - Reusable (Memory)
  - Consumable (Input/Time slice)

Fall 1999 : CS 3204 - Arthur

19

## Resource Descriptor

- Each Resource R has a Resource Descriptor associated with it (similar to the process)  
 => there is a "Status" for that Resource, and  
 => a Resource Manager to manage it

FIELD	DESCRIPTION
Internal resource name	An internal name for the resource used by the operating system code. <b>/dev/...</b>
Total units	The number of units of this resource type configured into the system. <b>6</b>
* Available units	The number of units currently available. <b>3</b>
List of available units	The set of available units of this resource type that are available for use by processes. <b>A, B, C</b>
List of blocked processes	The list of processes that have a pending request for units of this resource type. <b>Only if * = 0</b>

Fall 1999 : CS 3204 - Arthur

20

## Process Hierarchy

- Conceptually, this is the way in which we would like to view it
- Root controls all processes i.e. Parent

Fall 1999 : CS 3204 - Arthur

21

## Creating Processes

- Parent Process needs ability to
  - Block child
  - Activate child
  - Destroy child
  - Allocate resources to child
- True for User processes spawning child
- True for OS spawning *init*, *getty*, etc.
- Process hierarchy a natural, if *fork/exec* commands exist

Fall 1999 : CS 3204 - Arthur

22

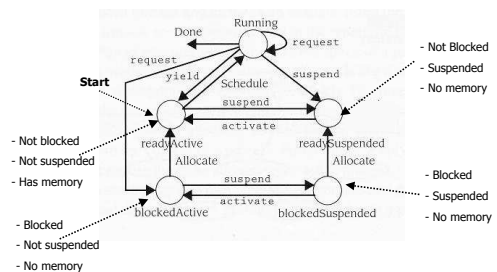

## Factoring in additional Control Complexities

- Recall:
  - A parent process can suspend a child process
- Therefore, if a child is in run state and goes to ready (time slice up), and the parent runs and decides to suspend the child, then how do we reflect this in the process state diagram ???
- We need 2 more states
  - Ready suspended
  - Blocked suspended

Fall 1999 : CS 3204 - Arthur

23

## Process State diagram reflecting Control

Fall 1999 : CS 3204 - Arthur

24

Give it a thought...

Why can a process NOT go from 'Ready Active' to 'Blocked Active' or 'Blocked Suspended' ?

Fall 1999 : CS 3204 - Arthur

25

## Process Management under Linux

Mir Farooq Ali

## Processes in Linux

- Also called *tasks*
- Task table or process table defined in `src/linux/include/sched.h`

```
extern struct task_struct
*pidhash[PIDHASH_SZ];
```
- Can also be accessed as a doubly-linked list `p->next_task` and `p->prev_task`

Fall 1999 : CS 3204 - Arthur

27

## Process or task descriptor

- Called `task_struct`
- Present in `src/include/linux/sched.h`
- Contains various fields to indicate
  - state
  - priority
  - pointers to parent, children, other tasks in pid list
  - tty
  - memory location
  - file descriptors
  - ...

Fall 1999 : CS 3204 - Arthur

28

## Process States

- Linux identifies following states
  1. `TASK_RUNNING`
  2. `TASK_INTERRUPTIBLE`
  3. `TASK_UNINTERRUPTIBLE`
  4. `TASK_ZOMBIE`
  5. `TASK_STOPPED`
  6. `TASK_EXCLUSIVE`

Fall 1999 : CS 3204 - Arthur

29

## Process Creation

- Remember in traditional UNIX, we use `fork()` and then typically `exec()`
- `fork()` duplicates resources owned by parent for child process and copies them to new address space
- This method is slow and inefficient, since `exec()` wipes out address space anyway

Fall 1999 : CS 3204 - Arthur

30

## Process creation in Linux

- Copy On Write technique
- Lightweight processes
- `vfork()`

Fall 1999 : CS 3204 - Arthur

31

## Copy-on-write

- Child pages are pointers to parent pages
- If child makes a change to a page, a new copy is made for the child
- This way, you avoid making separate copies of pages unnecessarily

Fall 1999 : CS 3204 - Arthur

32

## Lightweight processes

- Allow parent and child processes to share many kernel data structures
- created in Linux by function called `__clone()`
- uses non-standard `clone()` system call

Fall 1999 : CS 3204 - Arthur

33

## `vfork()`

- Creates a process that shares memory address of parent
- Parent is blocked until child exits or executes a new program by doing `exec()`

Fall 1999 : CS 3204 - Arthur

34

## User view of processes

- Can use `ps` command with various options, for example,
  - `ps -aux`
  - `ps -ef`

Fall 1999 : CS 3204 - Arthur

35

## `/proc` file system

- process information pseudo file system
- Do `man proc` to get more info
- `/proc` directory contains
  - Numerical subdirectory for each running process
  - A number of other files containing kernel table information

Fall 1999 : CS 3204 - Arthur

36

## /proc... continued

- Files include
  - cputime – contains CPU specs
  - uptime – time in secs since machine was last rebooted and idle time since then
  - version – kernel version
  - loadavg – Load average of machine over the past 1, 5 and 15 minutes
  - ...

Fall 1999 : CS 3204 - Arthur

37

## Process directories

- One subdirectory for each running process
- Files include
  - cmdline
  - cwd
  - environ
  - exe
  - fdm
  - map
  - mem
  - root

Fall 1999 : CS 3204 - Arthur
