Chapter 5: CPU Scheduling
Chapter 5: CPU Scheduling

- Basic Concepts
- Scheduling Criteria
- Scheduling Algorithms
- Multiple-Processor Scheduling
- Real-Time Scheduling
- Thread Scheduling
- Operating Systems Examples
- Java Thread Scheduling
- Algorithm Evaluation
Basic Concepts

- Maximum CPU utilization obtained with multiprogramming
- CPU–I/O Burst Cycle – Process execution consists of a cycle of CPU execution and I/O wait
- CPU burst distribution
Alternating Sequence of CPU And I/O Bursts

- load store
- add store
- read from file

wait for I/O

store increment index
write to file

wait for I/O

load store
add store
read from file

wait for I/O

- CPU burst
- I/O burst
- CPU burst
- I/O burst
- CPU burst
- I/O burst
Histogram of CPU-burst Times

[Diagram showing a histogram with frequency on the Y-axis and burst duration (milliseconds) on the X-axis.]
CPU Scheduler

- Selects from among the processes in memory that are ready to execute, and allocates the CPU to one of them.

- CPU scheduling decisions may take place when a process:
  1. Switches from running to waiting state
  2. Switches from running to ready state
  3. Switches from waiting to ready
  4. Terminates

- Scheduling under 1 and 4 is nonpreemptive

- All other scheduling is preemptive
Dispatcher module gives control of the CPU to the process selected by the short-term scheduler; this involves:

- switching context
- switching to user mode
- jumping to the proper location in the user program to restart that program

Dispatch latency – time it takes for the dispatcher to stop one process and start another running
Scheduling Criteria

- CPU utilization – keep the CPU as busy as possible
- Throughput – # of processes that complete their execution per time unit
- Turnaround time – amount of time to execute a particular process
- Waiting time – amount of time a process has been waiting in the ready queue
- Response time – amount of time it takes from when a request was submitted until the first response is produced, not output (for time-sharing environment)
Optimization Criteria

- Max CPU utilization
- Max throughput
- Min turnaround time
- Min waiting time
- Min response time
First-Come, First-Served (FCFS) Scheduling

<table>
<thead>
<tr>
<th>Process</th>
<th>Burst Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_1$</td>
<td>24</td>
</tr>
<tr>
<td>$P_2$</td>
<td>3</td>
</tr>
<tr>
<td>$P_3$</td>
<td>3</td>
</tr>
</tbody>
</table>

Suppose that the processes arrive in the order: $P_1, P_2, P_3$

The Gantt Chart for the schedule is:

```
0  24  27  30
P_1 P_2 P_3
```

- Waiting time for $P_1 = 0$; $P_2 = 24$; $P_3 = 27$
- Average waiting time: $(0 + 24 + 27)/3 = 17$
Suppose that the processes arrive in the order $P_2, P_3, P_1$.

- The Gantt chart for the schedule is:

<table>
<thead>
<tr>
<th></th>
<th>P₂</th>
<th>P₃</th>
<th>P₁</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>0</td>
<td>3</td>
<td>6</td>
</tr>
</tbody>
</table>

- Waiting time for $P_1 = 6$; $P_2 = 0$; $P_3 = 3$
- Average waiting time: $(6 + 0 + 3)/3 = 3$
- Much better than previous case
- *Convoy effect* short process behind long process
Shortest-Job-First (SJR) Scheduling

- Associate with each process the length of its next CPU burst. Use these lengths to schedule the process with the shortest time.

- Two schemes:
  - nonpreemptive – once CPU given to the process it cannot be preempted until completes its CPU burst
  - preemptive – if a new process arrives with CPU burst length less than remaining time of current executing process, preempt. This scheme is known as the Shortest-Remaining-Time-First (SRTF)

- SJF is optimal – gives minimum average waiting time for a given set of processes.
## Example of Non-Preemptive SJF

<table>
<thead>
<tr>
<th>Process</th>
<th>Arrival Time</th>
<th>Burst Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_1$</td>
<td>0.0</td>
<td>7</td>
</tr>
<tr>
<td>$P_2$</td>
<td>2.0</td>
<td>4</td>
</tr>
<tr>
<td>$P_3$</td>
<td>4.0</td>
<td>1</td>
</tr>
<tr>
<td>$P_4$</td>
<td>5.0</td>
<td>4</td>
</tr>
</tbody>
</table>

- **SJF (non-preemptive)**

![Process Schedule Diagram]

- Average waiting time = $(0 + 6 + 3 + 7)/4 = 4$
Example of Preemptive SJF

<table>
<thead>
<tr>
<th>Process</th>
<th>Arrival Time</th>
<th>Burst Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_1$</td>
<td>0.0</td>
<td>7</td>
</tr>
<tr>
<td>$P_2$</td>
<td>2.0</td>
<td>4</td>
</tr>
<tr>
<td>$P_3$</td>
<td>4.0</td>
<td>1</td>
</tr>
<tr>
<td>$P_4$</td>
<td>5.0</td>
<td>4</td>
</tr>
</tbody>
</table>

- SJF (preemptive)

Average waiting time = $\frac{9 + 1 + 0 + 2}{4} = 3$
Determining Length of Next CPU Burst

- Can only estimate the length
- Can be done by using the length of previous CPU bursts, using exponential averaging

1. \( t_n \) = actual length of \( n^{th} \) CPU burst
2. \( \tau_{n+1} \) = predicted value for the next CPU burst
3. \( \alpha, 0 \leq \alpha \leq 1 \)
4. Define: \( \tau_{n+1} = \alpha t_n + (1 - \alpha)\tau_n \).
Prediction of the Length of the Next CPU Burst

- CPU burst ($t_i$):
  - 6
  - 4
  - 6
  - 4
  - 13
  - 13
  - 13
  - ...

- "guess" ($\tau_i$):
  - 10
  - 8
  - 6
  - 6
  - 5
  - 9
  - 11
  - 12
  - ...

Diagram:
- Time axis
- Grid with data points
- Lines connecting data points

Equation:
\[ \text{Equation goes here.} \]
Examples of Exponential Averaging

- $\alpha = 0$
  - $\tau_{n+1} = \tau_n$
  - Recent history does not count
- $\alpha = 1$
  - $\tau_{n+1} = \alpha \cdot t_n$
  - Only the actual last CPU burst counts
- If we expand the formula, we get:
  $$\tau_{n+1} = \alpha \cdot t_n + (1 - \alpha) \cdot t_{n-1} + \ldots + (1 - \alpha)^j \cdot t_{n-j} + \ldots + (1 - \alpha)^{n+1} \cdot \tau_0$$
- Since both $\alpha$ and $(1 - \alpha)$ are less than or equal to 1, each successive term has less weight than its predecessor
Priority Scheduling

- A priority number (integer) is associated with each process
- The CPU is allocated to the process with the highest priority (smallest integer ≡ highest priority)
  - Preemptive
  - nonpreemptive
- SJF is a priority scheduling where priority is the predicted next CPU burst time
- Problem ≡ Starvation – low priority processes may never execute
- Solution ≡ Aging – as time progresses increase the priority of the process
Round Robin (RR)

- Each process gets a small unit of CPU time (*time quantum*), usually 10-100 milliseconds. After this time has elapsed, the process is preempted and added to the end of the ready queue.

- If there are *n* processes in the ready queue and the time quantum is *q*, then each process gets 1/*n* of the CPU time in chunks of at most *q* time units at once. No process waits more than (*n*-1)*q* time units.

- Performance
  
  - *q* large $\Rightarrow$ FIFO
  
  - *q* small $\Rightarrow$ *q* must be large with respect to context switch, otherwise overhead is too high.
Example of RR with Time Quantum = 20

<table>
<thead>
<tr>
<th>Process</th>
<th>Burst Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_1$</td>
<td>53</td>
</tr>
<tr>
<td>$P_2$</td>
<td>17</td>
</tr>
<tr>
<td>$P_3$</td>
<td>68</td>
</tr>
<tr>
<td>$P_4$</td>
<td>24</td>
</tr>
</tbody>
</table>

- The Gantt chart is:

```
0  20  37  57  77  97  117  121  134  154  162
```

- Typically, higher average turnaround than SJF, but better response
Time Quantum and Context Switch Time

- Process time = 10
- Quantum: 12, Context switches: 0
- Quantum: 6, Context switches: 1
- Quantum: 1, Context switches: 9
Turnaround Time Varies With The Time Quantum

<table>
<thead>
<tr>
<th>process</th>
<th>time</th>
</tr>
</thead>
<tbody>
<tr>
<td>$P_1$</td>
<td>6</td>
</tr>
<tr>
<td>$P_2$</td>
<td>3</td>
</tr>
<tr>
<td>$P_3$</td>
<td>1</td>
</tr>
<tr>
<td>$P_4$</td>
<td>7</td>
</tr>
</tbody>
</table>
Multilevel Queue

- Ready queue is partitioned into separate queues: foreground (interactive) and background (batch).
- Each queue has its own scheduling algorithm:
  - foreground – RR
  - background – FCFS
- Scheduling must be done between the queues:
  - Fixed priority scheduling; (i.e., serve all from foreground then from background). Possibility of starvation.
  - Time slice – each queue gets a certain amount of CPU time which it can schedule amongst its processes; i.e., 80% to foreground in RR
  - 20% to background in FCFS
Multilevel Queue Scheduling

- highest priority
  - system processes
- interactive processes
- interactive editing processes
- batch processes
- student processes

lowest priority
Multilevel Feedback Queue

- A process can move between the various queues; aging can be implemented this way.
- Multilevel-feedback-queue scheduler defined by the following parameters:
  - number of queues
  - scheduling algorithms for each queue
  - method used to determine when to upgrade a process
  - method used to determine when to demote a process
  - method used to determine which queue a process will enter when that process needs service
Example of Multilevel Feedback Queue

- Three queues:
  - $Q_0$ – RR with time quantum 8 milliseconds
  - $Q_1$ – RR time quantum 16 milliseconds
  - $Q_2$ – FCFS

- Scheduling
  - A new job enters queue $Q_0$ which is served FCFS. When it gains CPU, job receives 8 milliseconds. If it does not finish in 8 milliseconds, job is moved to queue $Q_1$.
  - At $Q_1$ job is again served FCFS and receives 16 additional milliseconds. If it still does not complete, it is preempted and moved to queue $Q_2$. 
Multilevel Feedback Queues

quantum = 8

quantum = 16

FCFS
Multiple-Processor Scheduling

- CPU scheduling more complex when multiple CPUs are available
- Homogeneous processors within a multiprocessor
- Load sharing
- Asymmetric multiprocessing – only one processor accesses the system data structures, alleviating the need for data sharing
Real-Time Scheduling

- **Hard real-time** systems – required to complete a critical task within a guaranteed amount of time
- **Soft real-time** computing – requires that critical processes receive priority over less fortunate ones
Thread Scheduling

- Local Scheduling – How the threads library decides which thread to put onto an available LWP

- Global Scheduling – How the kernel decides which kernel thread to run next
Pthread Scheduling API

#include <pthread.h>
#include <stdio.h>
#define NUM THREADS 5
int main(int argc, char *argv[])
{
    int i;
    pthread t tid[NUM THREADS];
    pthread attr t attr;
    /* get the default attributes */
    pthread attr init(&attr);
    /* set the scheduling algorithm to PROCESS or SYSTEM */
    pthread attr setscope(&attr, PTHREAD SCOPE SYSTEM);
    /* set the scheduling policy - FIFO, RT, or OTHER */
    pthread attr setschedpolicy(&attr, SCHED OTHER);
    /* create the threads */
    for (i = 0; i < NUM THREADS; i++)
        pthread create(&tid[i],&attr,runner,NULL);
Pthread Scheduling API

/* now join on each thread */
for (i = 0; i < NUM THREADS; i++)
    pthread join(tid[i], NULL);
}
/* Each thread will begin control in this function */
void *runner(void *param)
{
    printf("I am a thread\n");
    pthread exit(0);
}
Operating System Examples

- Solaris scheduling
- Windows XP scheduling
- Linux scheduling
Solaris 2 Scheduling

- Global priority: highest to lowest
- Scheduling order: first to last
- Class-specific priorities: real time
- Scheduler classes: system, interactive & time-sharing
- Run queue: kernel threads of real-time LWPs, kernel service threads, kernel threads of interactive & time-sharing LWPs
## Solaris Dispatch Table

<table>
<thead>

</tbody>
</table>
Linux Scheduling

- Two algorithms: time-sharing and real-time
  - Time-sharing
    - Prioritized credit-based – process with most credits is scheduled next
    - Credit subtracted when timer interrupt occurs
    - When credit = 0, another process chosen
    - When all processes have credit = 0, recrediting occurs
      - Based on factors including priority and history
  - Real-time
    - Soft real-time
    - Posix.1b compliant – two classes
      - FCFS and RR
      - Highest priority process always runs first
The Relationship Between Priorities and Time-slice length

<table>
<thead>
<tr>
<th>numeric priority</th>
<th>relative priority</th>
<th>time quantum</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>highest</td>
<td>200 ms</td>

Algorithm Evaluation

- Deterministic modeling – takes a particular predetermined workload and defines the performance of each algorithm for that workload
- Queueing models
- Implementation
5.15

- Actual process execution
  - CPU 10
  - I/O 213
  - CPU 12
  - I/O 112
  - CPU 2
  - I/O 147
  - CPU 173

- Trace tape

- Simulation
  - FCFS
  - SJF
  - RR (q = 14)

- Performance statistics for FCFS
- Performance statistics for SJF
- Performance statistics for RR (q = 14)

Dispatch Latency

Diagram showing the components of dispatch latency:
- Event
- Process made available
- Dispatch latency
- Conflicts
- Dispatch
- Real-time process execution
- Response interval
- Response to event
- Time
Java Thread Scheduling

- JVM Uses a Preemptive, Priority-Based Scheduling Algorithm

- FIFO Queue is Used if There Are Multiple Threads With the Same Priority
Java Thread Scheduling (cont)

JVM Schedules a Thread to Run When:

1. The Currently Running Thread Exits the Runnable State
2. A Higher Priority Thread Enters the Runnable State

* Note – the JVM Does Not Specify Whether Threads are Time-Sliced or Not
Since the JVM Doesn’t Ensure Time-Slicing, the yield() Method May Be Used:

```java
while (true) {
    // perform CPU-intensive task
    ...
    Thread.yield();
}
```

This Yields Control to Another Thread of Equal Priority
# Thread Priorities

<table>
<thead>
<tr>
<th>Priority</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>Thread.MIN_PRIORITY</td>
<td>Minimum Thread Priority</td>
</tr>
<tr>
<td>Thread.MAX_PRIORITY</td>
<td>Maximum Thread Priority</td>
</tr>
<tr>
<td>Thread.NORM_PRIORITY</td>
<td>Default Thread Priority</td>
</tr>
</tbody>
</table>

Priorities May Be Set Using `setPriority()` method:

```java
    setPriority(Thread.NORM_PRIORITY + 2);
```
