Factorial Growth (1)

Which function grows faster? $f(n) = 2^n$ or g(n) = n!

How about $h(n) = 2^{2n}$?

5 4104. Data and Algorithm
Analysis Fall 2010 43 / 69

Factorial Growth (1)

Which function grows faster? $f(n) = 2^n$ or g(n) = n!

How about $h(n) = 2^{2n}$?

								7	
g(n)	n!	1	2	6	24	120	720	5040	40320
f(n)	2^n	2	4	8	16	32	64	128	256
h(n)	2^{2n}	4	16	64	256	1024	4096	16384	65536

4104: Data and Algorithm
Analysis
Fall 2010 43 / 69

Factorial Growth (1)

Consider the recurrences:

$$h(n) = \begin{cases} 4 & n = 1 \\ 4h(n-1) & n > 1 \end{cases}$$

$$g(n) = \begin{cases} 1 & n = 1 \\ ng(n-1) & n > 1 \end{cases}$$

I hope your intuition tells you the right thing.

But, how do you PROVE it?

Induction? What is the base case?

4 D > 4 P > 4 E > 4 E > E 900

Analysis Fall 2010 44 / 69

Using Logarithms (1)

 $n! \ge 2^{2n}$ iff $\log n! \ge \log 2^{2n} = 2n$. Why?

Analysis Fall 2010 45 / 69

Using Logarithms (1)

$$n! \ge 2^{2n}$$
 iff $\log n! \ge \log 2^{2n} = 2n$. Why?

$$n! = n \times (n-1) \times \dots \times \frac{n}{2} \times (\frac{n}{2} - 1) \times \dots \times 2 \times 1$$

$$\geq \frac{n}{2} \times \frac{n}{2} \times \dots \times \frac{n}{2} \times 1 \times \dots \times 1 \times 1$$

$$= (\frac{n}{2})^{n/2}$$

S 4104. Data and Algorithm
Analysis Fall 2010 45 / 69

Using Logarithms (1)

$$n! \ge 2^{2n}$$
 iff $\log n! \ge \log 2^{2n} = 2n$. Why?

$$n! = n \times (n-1) \times \dots \times \frac{n}{2} \times (\frac{n}{2}-1) \times \dots \times 2 \times 1$$

$$\geq \frac{n}{2} \times \frac{n}{2} \times \dots \times \frac{n}{2} \times 1 \times \dots \times 1 \times 1$$

$$= (\frac{n}{2})^{n/2}$$

Therefore

$$\log n! \ge \log(\frac{n}{2})^{n/2} = (\frac{n}{2})\log(\frac{n}{2}).$$

Need only show that this grows to be bigger than 2n.

45 / 69

Using Logarithms (2)

$$\iff \frac{\binom{n}{2}\log(\frac{n}{2})}{\log(\frac{n}{2})} \geq 2n$$

$$\iff \log(\frac{n}{2}) \geq 4$$

$$\iff n \geq 32$$

So, $n! \ge 2^{2n}$ once $n \ge 32$.

Now we could prove this with induction, using 32 for the base case.

- What is the tightest base case?
- How did we get such a big over-estimate?

4 D > 4 D > 4 D > 4 D > 3 P 9 Q Q

Logs and Factorials

We have proved that $n! \in \Omega(2^{2n})$.

We have also proved that $\log n! \in \Omega(n \log n)$.

From here, its easy to prove that $\log n! \in O(n \log n)$, so $\log n! = \Theta(n \log n)$.

This does **not** mean that $n! = \Theta(n^n)$.

- Note that $\log n = \Theta(\log n^2)$ but $n \neq \Theta(n^2)$.
- The log function is a "flattener" when dealing with asymptotics.

《□▶ 《□▶ 《□▶ 《□▶ 《□ 》 ○

```
sum = 0; inc = 0;
for (i=1; i<=n; i++)
  for (j=1; j<=i; j++) {
    sum = sum + inc;
    inc++;
}</pre>
```

Use summations to analyze this code fragment. The number of assignments is:

$$2 + \sum_{i=1}^{n} (\sum_{j=1}^{i} 2) = 2 + \sum_{i=1}^{n} 2i = 2 + 2 \sum_{i=1}^{n} i$$

SAMM: Data and Macrithm

Give a good estimate.

Observe that we can "pair up" the first and last terms, the 2nd and (n-1)th terms, and so on. Each pair sums to: n+1.

The number of pairs is: n/2.

Thus, the solution is:

9 4104. Data and Algorithm
Analysis Fall 2010 50 / 69

Observe that we can "pair up" the first and last terms, the 2nd and (n-1)th terms, and so on. Each pair sums to: n+1.

The number of pairs is: n/2.

Thus, the solution is: (n+1)(n/2).

9 4104: Data and Algorithm
Analysis Fall 2010 50 / 69

A Little More General

Since the largest term is n and there are n terms, the summation is less than n^2 .

If we are lucky, the solution is a polynomial.

Guess:
$$f(n) = c_1 n^2 + c_2 n + c_3$$
.

$$f(0) = 0$$
 so $c_3 = 0$.

For
$$f(1)$$
, we get $c_1 + c_2 = 1$.

For
$$f(2)$$
, we get $4c_1 + 2c_2 = 3$.

Setting this up as a system of 2 equations on 2 variables, we can solve to find that $c_1 = 1/2$ and $c_2 = 1/2$.

CANAL Data and Algorithm

More General (2)

So, if it truely is a polynomial, it must be

$$f(n) = n^2/2 + n/2 + 0 = \frac{n(n+1)}{2}$$
.

Use induction to prove. Why is this step necessary?

Why is this not a universal approach to solving summations?

6 4104: Data and Algorithm
Analysis
Fall 2010 52 / 69

An Even More General Approach

Subtract-and-Guess or Divide-and-Guess strategies.

To solve sum f, pick a known function g and find a pattern in terms of f(n) - g(n) or f(n)/g(n).

Find the closed form solution for

$$f(n) = \sum_{i=1}^{n} i.$$

Guessing (cont.)

Examples: Try $g_1(n) = n$; $g_2(n) = f(n-1)$.

n	1	2	3	4	5	6	7	8
f(n)	1	3	6	10	15	21	28	36
$g_1(n)$	1	2	3	4	5	6	7	8
$g_1(n)$ $f(n)/g_1(n)$	2/2	3/2	4/2	5/2	6/2	7/2	8/2	9/2
$g_2(n)$	0	1	3	6	10	15	21	28
$f(n)/g_2(n)$		3/1	4/2	5/3	6/4	7/5	8/6	9/7

What are the patterns?

$$\frac{f(n)}{g_1(n)} = \frac{f(n)}{g_2(n)} = \frac{f(n)}{g_2(n)} = \frac{f(n)}{g_2(n)} = \frac{f(n)}{g_2(n)}$$

4 D > 4 D > 4 E > 4 E > E 990

Solving Summations (cont.)

Use algebra to rearrange and solve for f(n)

$$\frac{f(n)}{n}=\frac{n+1}{2}$$

$$\frac{f(n)}{f(n-1)} = \frac{n+1}{n-1}$$

55 / 69

DS 4104. Data and Algorithm
Analysis Fall 2010

Solving Summations (cont.)

$$\frac{f(n)}{f(n-1)} = \frac{n+1}{n-1}$$

$$f(n)(n-1) = (n+1)f(n-1)$$

$$f(n)(n-1) = (n+1)(f(n)-n)$$

$$nf(n) - f(n) = nf(n) + f(n) - n^2 - n$$

$$2f(n) = n^2 + n = n(n+1)$$

$$f(n) = \frac{n(n+1)}{2}$$

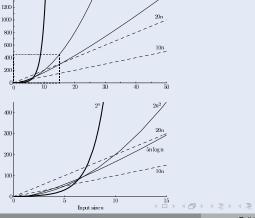

Important Note: This is **not a proof** that f(n) = n(n+1)/2. Why?

I. Data and Algorithm
Analysis Fall 2010 56 / 69

Growth Rates

Two functions of n have different **growth rates** if as n goes to infinity their ratio either goes to infinity or goes to zero.

1400

 $5n \log n$

Estimating Growth Rates

Exact equations relating program operations to running time require machine-dependent constants.

Sometimes, the equation for exact running time is complicated to compute.

Usually, we are satisfied with knowing an approximate growth rate.

Example: Given two algorithms with growth rate $c_1 n$ and $c_2 2^{n!}$, do we need to know the values of c_1 and c_2 ?

Consider n^2 and 3n. PROVE that n^2 must eventually become (and remain) bigger.

Analysis Fall 2010 58 / 69

Proof by Contradiction

Assume there are some values for constants r and s such that, for all values of n,

$$n^2 < rn + s$$
.

Then, n < r + s/n.

But, as *n* grows, what happens to s/n?

Since *n* grows toward infinity, the assumption must be false.

Some Growth Rates (1)

Since n^2 grows faster than n,

- 2^{n^2} grows faster than 2^n .
- n^4 grows faster than n^2 .
- n grows faster than \sqrt{n} .
- 2 log *n* grows <u>no slower</u> than log *n*.

◆ロト ◆個 ト ◆ 恵 ト ◆ 恵 ・ 夕 へ ○

Fall 2010

60/69

Some Growth Rates (2)

Since n! grows faster than 2^n ,

- n!! grows faster than $2^n!$.
- $2^{n!}$ grows faster than 2^{2^n} .
- $n!^2$ grows faster than 2^{2n} .
- $\sqrt{n!}$ grows faster than $\sqrt{2^n}$.
- log n! grows no slower than n.

Fall 2010

61 / 69

Some Growth Rates (3)

If f grows faster than q, then

- Must \sqrt{f} grow faster than \sqrt{g} ?
- Must log f grow faster than log g?

log *n* is related to *n* in exactly the same way that *n* is related to 2^n .

•
$$2^{\log n} = n$$

Fibonacci Numbers (Iterative)

```
f(n) = f(n-1) + f(n-2) for n \ge 2; f(0) = f(1) = 1.
```

The cost of Fibi is easy to compute:

4 D > 4 P > 4 B > 4 B > B 9 9 P

Fall 2010

63 / 69

Fibonacci Numbers (Recursive)

```
int Fibr(int n) {
 if ((n <= 1) return 1;
                                   // Base case
 return Fibr(n-1) + Fibr(n-2);
                                   // Recursive call
```

What is the cost of Fibr?

Analysis of Fibr

Use divide-and-guess with f(n-1).

n
 1
 2
 3
 4
 5
 6
 7

$$f(n)$$
 1
 2
 3
 5
 8
 13
 21

 $f(n)/f(n-1)$
 1
 2
 1.5
 1.666
 1.625
 1.615
 1.619

Following this out, it appears to settle to a ratio of 1.618.

Assuming f(n)/f(n-1) really tends to a fixed value x, let's verify what x must be.

$$\frac{f(n)}{f(n-2)} = \frac{f(n-1)}{f(n-2)} + \frac{f(n-2)}{f(n-2)} \to x+1$$

65 / 69

Analysis Fall 2010

Analysis of Fibr (cont.)

For large *n*,

$$\frac{f(n)}{f(n-2)} = \frac{f(n)}{f(n-1)} \frac{f(n-1)}{f(n-2)} \to x^2$$

If x exists, then $x^2 - x - 1 \rightarrow 0$.

Using the quadratic equation, the only solution greater than one is

$$x = \frac{1 + \sqrt{5}}{2} \approx 1.618.$$

What does this say about the growth rate of *f*?

4. Data and Algorithm
Analysis Fall 2010 66 / 69

Order Notation

• While $n \in O(n^2)$ and $n^2 \in O(n^2)$, $O(n) \neq O(n^2)$.

Note: Big oh does not say how good an algorithm is – only how bad it CAN be.

If
$$A \in O(n)$$
 and $B \in O(n^2)$, is A better than B ?

Perhaps... but perhaps better analysis will show that $A = \Theta(n)$ while $B = \Theta(\log n)$.

Limitations on Order Notation

Statement: Algorithm \mathcal{A} 's resource requirements grow slower than Algorithm \mathcal{B} 's resource requirements.

Is A better than B?

Potential problems:

- How big must the input be?
- Some growth rate differences are trivial
 - ► Example: $\Theta(\log^2 n)$ vs. $\Theta(n^{1/10})$.
- It is not always practical to reduce an algorithm's growth rate
 - Shaving a factor of n reduces cost by a factor of a million for input size of a million.
 - ► Shaving a factor of log log *n* saves only a factor of 4-5.

Batta and Angioratini Analysis Fall 2010 68 / 69

Practicality Window

In general:

- We have limited time to solve a problem.
- We have a limited input size.

Fortunately, algorithm growth rates are USUALLY well behaved, so that Order Notation gives practical indications.

69 / 69

CS 4104: Data and Algorithm
Analysis Fall 2010

Searching

Assumptions for search problems:

- Target is well defined.
- Target is fixed.
- Search domain is finite.
- We (can) remember all information gathered during search.

We search for a record with a **key**.

A Search Model (1)

Problem:

Given:

- A list L, of n elements
- A search key X

Solve: Identify one element in *L* which has key value *X*, if any exist.

Analysis

A Search Model (1)

Problem:

Given:

- A list *L*, of *n* elements
- A search key X

Solve: Identify one element in *L* which has key value *X*, if any exist.

Model:

Analysis

- The key values for elements in *L* are unique.
- One comparison determines <, =, >.
- Comparison is our only way to find ordering information.
- Every comparison costs the same.

→ Pais and Algorithm → マロト・ヨト・ヨー・クスで

Fall 2010

A Search Model (2)

Goal: Solve the problem using the minimum number of comparisons.

- Cost model: Number of comparisons.
- (Implication) Access to every item in L costs the same (array).

Is this a reasonable model and goal?

◆ロ > ◆回 > ◆ 豆 > ◆豆 > ・ 豆 ・ 夕 Q ○

Linear Search

General algorithm strategy: Reduce the problem.

- Compare X to the first element.
- If not done, then solve the problem for n-1 elements.

```
Position linear_search(L, lower, upper, X) {
  if L[lower] = X then
    return lower;
  else if lower = upper then
    return -1;
  else
    return linear_search(L, lower+1, upper, X);
}
```

What equation represents the worst case cost?

Analysis Fall 2010 73 / 69

Worst Cost Upper Bound

$$f(n) = \begin{cases} 1 & n = 1 \\ f(n-1) + 1 & n > 1 \end{cases}$$

Reasonable to guess that f(n) = n.

Prove by induction:

Basis step: f(1) = 1, so f(n) = n when n = 1.

Induction hypothesis: For k < n, f(k) = k.

Induction step: From recurrence,

$$f(n) = f(n-1)+1$$

= $(n-1)+1$
= n

Thus, the worst case cost for *n* elements is linear. Induction is great for verifying a hypothesis.

Analysis Fall 2010 74 / 69

Approach #2

- What if we couldn't guess a solution?
- Try: Substitute and Guess.
 - Iterate a few steps of the recurrence, and look for a summation.

$$f(n) = f(n-1)+1$$

$$= \{f(n-2)+1\}+1$$

$$= \{\{f(n-3)+1\}+1\}+1\}$$

- Now what? Guess f(n) = f(n-i) + i.
- When do we stop? When we reach a value for f that we know.

$$f(n) = f(n-(n-1)) + n - 1 = f(1) + n - 1 = n$$

• Now, go back and test the guess using induction.

1 = 340

Approach #3

Guess and Test: Guess the form of the solution, then solve the resulting equations.

Guess: f(n) is linear.

$$f(n) = rn + s$$
 for some r, s .

What do we know?

- f(1) = r(1) + s = r + s = 1.
- f(n) = r(n) + s = r(n-1) + s + 1.

Solving these two simultaneous equations, r = 1, s = 0.

Final form of guess: f(n) = n.

Now, prove using induction.

Analysis Fall 2010 76 / 69

Lower Bound on Problem

Theorem: Lower bound (in the worst case) for the problem is *n* comparisons.

Proof: By contradiction.

- Assume an algorithm A exists that requires only n-1 (or less) comparisons of X with elements of L.
- Since there are n elements of L, A must have avoided comparing X with L[i] for some value i.
- We can feed the algorithm an input with X in position i.
- Such an input is legal in our model, so the algorithm is incorrect.

Is this proof correct?

Analysis Fall 2010 77 / 69

Fixing the Proof (1)

Error #1: An algorithm need not consistently skip position *i*. Fix:

- On any given run of the algorithm, some element i gets skipped.
- It is possible that *X* is in position *i* at that time.

S 4104: Data and Algorithm
Analysis Fall 2010 78 / 69

Fixing the Proof (2)

Error #2: Must allow comparisons between elements of *L*. Fix:

- Include the ability to "preprocess" L.
- View L as initially consisting of n "pieces."
- A comparison can join two pieces (without involving *X*).
- The total of these comparisons is *k*.
- We must have at least n k pieces.
- A comparison of X against a piece can reject the whole piece.
- This requires n k comparisons.
- The total is still at least *n* comparisons.

6 4104: Data and Algorithm Analysis Fall 2010 79 / 69

Average Cost

How many comparisons does linear search do on average?

We must know the probability of occurrence for each possible input.

(Must X be in L?) Ignore everything except the position of X

in L. Why?

Analysis

What are the n + 1 events?

$$P(X \notin L) = 1 - \sum_{i=1}^{n} P(X = L[i]).$$

Fall 2010

Average Cost Equation

Let $k_i = i$ be the number of comparisons when X = L[i]. Let $k_0 = n$ be the number of comparisons when $X \notin L$.

Let p_i be the probability that X = L[i]. Let p_0 be the probability that $X \notin L[i]$ for any i.

$$f(n) = k_0 p_0 + \sum_{i=1}^{n} k_i p_i$$

= $np_0 + \sum_{i=1}^{n} ip_i$

What happens to the equation if we assume all p_i 's are equal (except p_0)?

Guard (except po):

Data and Algorithm
Analysis

Fall 2010 81/69

Computation

$$f(n) = p_0 n + \sum_{i=1}^{n} i p$$

$$= p_0 n + p \sum_{i=1}^{n} i$$

$$= p_0 n + p \frac{n(n+1)}{2}$$

$$= p_0 n + \frac{1 - p_0}{n} \frac{n(n+1)}{2}$$

$$= \frac{n+1 + p_0(n-1)}{2}$$

Depending on the value of p_0 , $\frac{n+1}{2} \le f(n) \le n$.

Analysis Fall 2010 82 / 69

Problems with Average Cost

- Average cost is usually harder to determine than worst cost.
- We really need also to know the variance around the average.
- Our computation is only as good as our knowledge (guess) on distribution.

83 / 69

5 4104: Data and Algorithm
Analysis Fall 2010

Sorted List

Change the model: Assume that the elements are in ascending order.

Is linear search still optimal? Why not?

Optimization: Use linear search, but test if the element is greater than X. Why?

Observation: If we look at L[5] and find that X is bigger, then we rule out L[1] to L[4] as well.

More is Better: If we look at L[n] and find that X is bigger, then we know in one test that X is not in L. Great!

• What is wrong here?

Analysis

Jump Search

Algorithm:

- From the beginning of the array, start making jumps of size k, checking L[k] then L[2k], and so on.
- So long as X is greater, keep jumping by k.
- If X is less, then use linear search on the last sublist of k elements.

This is called Jump Search.

What is the right amount to jump?

Analysis of Jump Search

• If $mk \le n < (m+1)k$, then the total cost is at most m+k-1 3-way comparisons.

$$f(n,k)=m+k-1=\left\lfloor\frac{n}{k}\right\rfloor+k-1.$$

• What should k be?

$$\min_{1 \le k \le n} \left\{ \left\lfloor \frac{n}{k} \right\rfloor + k - 1 \right\}$$

- Take the derivative and solve for f'(x) = 0 to find the minimum.
- This is a minimum when $k = \sqrt{n}$.
- What is the worst case cost?
 - ▶ Roughly $2\sqrt{n}$.

86 / 69

Analysis Fall 2010

Lessons

We want to balance the work done while selecting a sublist with the work done while searching a sublist.

In general, make subproblems of equal effort.

This is an example of divide and conquer

What if we extend this to three levels?

- We'd jump to get a sublist, then jump to get a sub-sublist, then do sequential search
- While it might make sense to do a two-level algorithm (like jump search), it almost never makes sense to do a three-level algorithm
- Instead, we resort to recursion

<ロ > < @ > < 重 > < 重 > 重 の < @ >

Binary Search

```
int binary(int K, int* array, int left, int right) {
 // Return position of element (if any) with value K
 int l = left-1;
 int r = right+1; // l and r beyond array bounds
 while (l+1 != r) \{ // Stop when 1 and r meet
   int i = (1+r)/2; // Middle of remaining subarray
   if (K < array[i]) r = i; // In left half
   if (K == array[i]) return i; // Found it
   if (K > array[i]) l = i;  // In right half
 return UNSUCCESSFUL; // Search value not in array
```

Worst Case for Binary Search (1)

$$f(n) = \begin{cases} 1 & n = 1 \\ f(\lfloor n/2 \rfloor) + 1 & n > 1 \end{cases}$$

Since $n/2 \ge \lfloor n/2 \rfloor$, and since f(n) is assumed to be non-decreasing (why?), we can use

$$f(n) = f(n/2) + 1.$$

Alternatively, assume *n* is a power of 2.

Expand the recurrence:

Analvsis

$$f(n) = f(n/2) + 1$$

$$= \{f(n/4) + 1\} + 1$$

$$= \{\{f(n/8) + 1\} + 1\} + 1$$

Fall 2010 89 / 69

Worst Case for Binary Search (2)

Collapse to

$$f(n) = f(n/2^i) + i = \log n + 1$$

Now, prove it with induction.

$$f(n/2) + 1 = (\log(n/2) + 1) + 1$$

= $(\log n - 1 + 1) + 1$
= $\log n + 1 = f(n)$.

Analysis Fall 2010 90 / 69

Lower Bound (for Problem Worst Case)

How does *n* compare to \sqrt{n} compare to $\log n$?

Can we do better?

Model an algorithm for the problem using a decision tree.

- Consider only comparisons with X.
- Branch depending on the result of comparing X with L[i].
- There must be at least *n* leaf nodes in the tree. (Why?)
- Some path must be at least log n deep. (Why?)

Thus, binary search has optimal worst cost under this model.

4. Data and Algorithm
Analysis Fall 2010 91 / 69

Average Cost of Binary Search (1)

An estimate given these assumptions:

- X is in L.
- X is equally likely to be in any position.
- $n = 2^k$ for some non-negative integer k.

Cost?

Analysis

Average Cost of Binary Search (1)

An estimate given these assumptions:

- X is in L.
- X is equally likely to be in any position.
- $n = 2^k$ for some non-negative integer k.

Cost?

- One chance to hit in one probe.
- Two chances to hit in two probes.
- 2^{i-1} to hit in *i* probes.
- $i \leq k$.

Analysis Fall 2010

Average Cost (2)

$$\frac{1 \times 1 + 2 \times 2 + 3 \times 4 + \dots + \log n 2^{\log n - 1}}{n} = \frac{1}{n} \sum_{i=1}^{\log n} i 2^{i - 1}$$

$$\sum_{i=1}^{k} i2^{i-1} = \sum_{i=0}^{k-1} (i+1)2^{i} = \sum_{i=0}^{k-1} i2^{i} + \sum_{i=0}^{k-1} 2^{i}$$
$$= 2\sum_{i=0}^{k-1} i2^{i-1} + 2^{k} - 1$$
$$= 2\sum_{i=0}^{k} i2^{i-1} - k2^{k} + 2^{k} - 1$$

5 4104. Data and Algorithm
Analysis Fall 2010 93 / 69

Average Cost (3)

Now what? Subtract from the original!

$$\sum_{i=1}^{k} i2^{i-1} = k2^k - 2^k + 1 = (k-1)2^k + 1.$$

S 4104. Data and Algorithm
Analysis
Fall 2010 94 / 69

Result (1)

$$\frac{1}{n} \sum_{i=1}^{\log n} i 2^{i-1} = \frac{(\log n - 1) 2^{\log n} + 1}{n}$$
$$= \frac{n(\log n - 1) + 1}{n}$$
$$\approx \log n - 1$$

So the average cost is only about one or two comparisons less than the worst cost.

Analysis

Result (2)

If we want to relax the assumption that $n = 2^k$, we get:

$$f(n) = \begin{cases} 0 & n = 0 \\ 1 & n = 1 \\ \frac{\lceil \frac{n}{2} \rceil - 1}{n} f(\lceil \frac{n}{2} \rceil - 1) + \frac{1}{n} 0 + \\ \frac{\lfloor \frac{n}{2} \rfloor}{n} f(\lfloor \frac{n}{2} \rfloor) + 1 & n > 1 \end{cases}$$

03 4104: Data and Algorithm
Analysis
Fall 2010

Average Cost Lower Bound

- Use decision trees again.
- Total Path Length: Sum of the level for each node.
- The cost of an outcome is the level of the corresponding node plus 1.
- The average cost of the algorithm is the average cost of the outcomes (total path length/n).
- What is the tree with the least average depth?
- This is equivalent to the tree that corresponds to binary search.
- Thus, binary search is optimal.

4 D > 4 D > 4 E > 4 E > E 900

Changing the Model

What are factors that might make binary search either unusable or not optimal?

- We know something about the distribution.
- Data are not sorted. (Preprocessing?)
- Data sorted, but probes not all the same cost (not an array).
- Data are static, know all search requests in advance.

Interpolation Search

(Also known as Dictionary Search)

Search *L* at a position that is appropriate to the value of *X*.

$$\rho = \frac{X - L[1]}{L[n] - L[1]}$$

Repeat as necessary to recalculate *p* for future searches.

99 / 69

CS 4104. Data and Algorithm
Analysis Fall 2010

Quadratic Binary Search

This is easier to analyze:

- Compute p and examine $L[\lceil pn \rceil]$.
- If $X < L[\lceil pn \rceil]$ then sequentially probe

$$L[\lceil pn - i\sqrt{n} \rceil], i = 1, 2, 3, ...$$

until we reach a value less than or equal to X.

- Similar for $X > L[\lceil pn \rceil]$.
- We are now within \sqrt{n} positions of X.
- ASSUME (for now) that this takes a constant number of comparisons.
- Now we have a sublist of size \sqrt{n} .
- Repeat the process recursively.
- What is the cost?

4 ロ ト 4 昼 ト 4 夏 ト 4 夏 ト 9 Q (C)

QBS Probe Count (1)

Cost is $\Theta(\log \log n)$ IF the number of probes on jump search is constant.

Number of comparisons needed is:

$$\sum_{i=1}^{\sqrt{n}} i \mathbf{P}(\text{need exactly } i \text{ probes})$$
$$= 1 \mathbf{P}_1 + 2 \mathbf{P}_2 + 3 \mathbf{P}_3 + \dots + \sqrt{n} \mathbf{P}_{\sqrt{n}}$$

This is equal to:

$$\sum_{i=1}^{\sqrt{n}} \mathbf{P}(\text{need at least } i \text{ probes})$$

QBS Probe Count (2)

$$\sum_{i=1}^{\sqrt{n}} \mathbf{P}(\text{need at least } i \text{ probes})$$

=
$$1 + (1 - \mathbf{P}_1) + (1 - \mathbf{P}_1 - \mathbf{P}_2) + \dots + \mathbf{P}_{\sqrt{n}}$$

= $(\mathbf{P}_1 + \dots + \mathbf{P}_{\sqrt{n}}) + (\mathbf{P}_2 + \dots + \mathbf{P}_{\sqrt{n}}) + (\mathbf{P}_3 + \dots + \mathbf{P}_{\sqrt{n}}) + \dots$
= $1\mathbf{P}_1 + 2\mathbf{P}_2 + 3\mathbf{P}_3 + \dots + \sqrt{n}\mathbf{P}_{\sqrt{n}}$

◆ロト ◆卸 → ◆ 重 ト ◆ 重 ・ り Q G

4104: Data and Algorithm
Analysis Fall 2010 102 / 69

QBS Probe Count (3)

We require at least two probes to set the bounds, so cost is:

$$2 + \sum_{i=3}^{\sqrt{n}} \mathbf{P}(\text{need at least } i \text{ probes})$$

Useful fact (Čebyšev's Inequality):

The probability that we need probe i times (\mathbf{P}_i) is:

$$\mathbf{P}_i \le \frac{p(1-p)n}{(i-2)^2n} \le \frac{1}{4(i-2)^2}$$

since $p(1 - p) \le 1/4$.

This assumes uniformly distributed data.

94: Data and Algorithm
Analysis Fall 2010 103 / 69

QBS Probe Count (4)

Final result:

$$2 + \sum_{i=3}^{\sqrt{n}} \frac{1}{4(i-2)^2} \approx 2.4112$$

Is this better than binary search?

What happened to our proof that binary search is optimal?

◆ロト ◆個 ト ◆ 恵 ト ◆ 恵 ・ 夕 へ ○

6 4104. Data and Algorithm Analysis Fall 2010 104 / 69

Comparison (1)

Let's compare $\log \log n$ to $\log n$.

n	log n	log log n	Diff
16	4	2	2
256	8	3	2.7
64 <i>K</i>	16	4	4
2 ³²	32	5	6.4

Now look at the actual comparisons used.

- Binary search $\approx \log n 1$
- Interpolation search $\approx 2.4 \log \log n$

n	log <i>n</i> – 1	2.4 log log <i>n</i>	Diff
16	3	4.8	worse
256	7	7.2	\approx same
64 <i>K</i>	15	9.6	1.6
2 ³²	31	12	2.6

) 4164. Data and Algorithm Analysis Fall 2010 105 / 69

Comparison (2)

Not done yet! This is only a count of comparisons!

Which algorithm is dependent on good behavior by the input?

106 / 69

Analysis Fall 2010

Hashing

Assume we can preprocess the data.

• How should we do it to minimize search?

Put record with key value X in L[X].

If the range is too big, then use hashing.

How much can we get from this?

Simplifying assumptions:

- We hash to each slot with equal probability
- We probe to each (new) slot with equal probability
- This is called uniform hashing

4 ロ ト 4 昼 ト 4 夏 ト 1 夏 1 り 4 0

Hashing Insertion Analysis (1)

Define $\alpha = N/M$ (Records stored/Table size)

Insertion cost: sum of costs times probabilities for looking at 1, 2, ..., N + 1 slots

- Probability of collision on insertion? $\alpha = N/M$
- \bullet Probability of initial collision and another collision when probing? α^2

$$\sum_{i=0}^{i=N} i(\frac{N}{M})^i \frac{M-N}{M} = \sum_{i=0}^{i=N} i\alpha^i (1-\alpha)$$

Analysis Fall 2010

Hashing Insertion Analysis (2)

Simpler formulation: Always look at least once, look at least twice with probability α , look at least three times with probability α^2 , etc.

$$\sum_{i=0}^{\infty} \alpha^{i} = 1 + \alpha + \alpha^{2} \cdots = \frac{1}{1 - \alpha}$$

How does this grow?
