# Dynamic Programming 

T. M. Murali

February 28, March 5, 17, 19, 21, 2013

## Algorithm Design Techniques

1. Goal: design efficient (polynomial-time) algorithms.

## Algorithm Design Techniques

1. Goal: design efficient (polynomial-time) algorithms.
2. Greedy

- Pro: natural approach to algorithm design.
- Con: many greedy approaches to a problem. Only some may work.
- Con: many problems for which no greedy approach is known.

## Algorithm Design Techniques

1. Goal: design efficient (polynomial-time) algorithms.
2. Greedy

- Pro: natural approach to algorithm design.
- Con: many greedy approaches to a problem. Only some may work.
- Con: many problems for which no greedy approach is known.

3. Divide and conquer

- Pro: simple to develop algorithm skeleton.
- Con: conquer step can be very hard to implement efficiently.
- Con: usually reduces time for a problem known to be solvable in polynomial time.

## Algorithm Design Techniques

1. Goal: design efficient (polynomial-time) algorithms.
2. Greedy

- Pro: natural approach to algorithm design.
- Con: many greedy approaches to a problem. Only some may work.
- Con: many problems for which no greedy approach is known.

3. Divide and conquer

- Pro: simple to develop algorithm skeleton.
- Con: conquer step can be very hard to implement efficiently.
- Con: usually reduces time for a problem known to be solvable in polynomial time.

4. Dynamic programming

- More powerful than greedy and divide-and-conquer strategies.
- Implicitly explore space of all possible solutions.
- Solve multiple sub-problems and build up correct solutions to larger and larger sub-problems.
- Careful analysis needed to ensure number of sub-problems solved is polynomial in the size of the input.

## History of Dynamic Programming

- Bellman pioneered the systematic study of dynamic programming in the 1950s.

## History of Dynamic Programming

- Bellman pioneered the systematic study of dynamic programming in the 1950s.
- The Secretary of Defense at that time was hostile to mathematical research.
- Bellman sought an impressive name to avoid confrontation.
- "it's impossible to use dynamic in a pejorative sense"
- "something not even a Congressman could object to" (Bellman, R. E., Eye of the Hurricane, An Autobiography).

## Applications of Dynamic Programming

- Computational biology: Smith-Waterman algorithm for sequence alignment.
- Operations research: Bellman-Ford algorithm for shortest path routing in networks.
- Control theory: Viterbi algorithm for hidden Markov models.
- Computer science (theory, graphics, AI, ...): Unix diff command for comparing two files.

## Review: Interval Scheduling

Interval Scheduling
INSTANCE: Nonempty set $\left\{\left(s_{i}, f_{i}\right), 1 \leq i \leq n\right\}$ of start and finish times of $n$ jobs.
SOLUTION: The largest subset of mutually compatible jobs.

- Two jobs are compatible if they do not overlap.

## Review: Interval Scheduling

Interval Scheduling
INSTANCE: Nonempty set $\left\{\left(s_{i}, f_{i}\right), 1 \leq i \leq n\right\}$ of start and finish times of $n$ jobs.
SOLUTION: The largest subset of mutually compatible jobs.

- Two jobs are compatible if they do not overlap.
- Greedy algorithm: sort jobs in increasing order of finish times. Add next job to current subset only if it is compatible with previously-selected jobs.

## Weighted Interval Scheduling

Weighted Interval Scheduling
INSTANCE: Nonempty set $\left\{\left(s_{i}, f_{i}\right), 1 \leq i \leq n\right\}$ of start and finish times of $n$ jobs and a weight $v_{i} \geq 0$ associated with each job.

SOLUTION: A set $S$ of mutually compatible jobs such that $\sum_{i \in S} v_{i}$ is maximised.

Figure 6.1 A simple instance of weighted interval scheduling.

- Greedy algorithm can produce arbitrarily bad results for this problem.

## Approach

- Sort jobs in increasing order of finish time and relabel: $f_{1} \leq f_{2} \leq \ldots \leq f_{n}$.
- Job $i$ comes before job $j$ if $i<j$.
- $p(j)$ is the largest index $i<j$ such that job $i$ is compatible with job $j$. $p(j)=0$ if there is no such job $i$.
- All jobs that come before job $p(j)$ are also compatible with job $j$.

Figure 6.2 An instance of weighted interval scheduling with the functions $p(j)$ defined for each interval $j$.

- We will develop optimal algorithm from obvious statements about the problem.

## Detour: a Binomial Identity

## Detour: a Binomial Identity

- Pascal's triangle:
- Each element is a binomial co-efficient.
- Each element is the sum of the two elements above it.

## Detour: a Binomial Identity

- Pascal's triangle:
- Each element is a binomial co-efficient.
- Each element is the sum of the two elements above it.

$$
\binom{n}{r}=\binom{n-1}{r-1}+\binom{n-1}{r}
$$

## Detour: a Binomial Identity

- Pascal's triangle:
- Each element is a binomial co-efficient.
- Each element is the sum of the two elements above it.

$$
\binom{n}{r}=\binom{n-1}{r-1}+\binom{n-1}{r}
$$

- Proof: either we select the $n$th element or not ...

## Sub-problems

- Let $\mathcal{O}$ be the optimal solution. Two cases to consider. Case 1 job $n$ is not in $\mathcal{O}$.

Case 2 job $n$ is in $\mathcal{O}$.

## Sub-problems

- Let $\mathcal{O}$ be the optimal solution. Two cases to consider. Case 1 job $n$ is not in $\mathcal{O}$. $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, n-1\}$. Case 2 job $n$ is in $\mathcal{O}$.

## Sub-problems

- Let $\mathcal{O}$ be the optimal solution. Two cases to consider. Case 1 job $n$ is not in $\mathcal{O}$. $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, n-1\}$.
Case 2 job $n$ is in $\mathcal{O}$.
- $\mathcal{O}$ cannot use incompatible jobs
$\{p(n)+1, p(n)+2, \ldots, n-1\}$.
- Remaining jobs in $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, p(n)\}$.

## Sub-problems

- Let $\mathcal{O}$ be the optimal solution. Two cases to consider. Case 1 job $n$ is not in $\mathcal{O}$. $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, n-1\}$. Case 2 job $n$ is in $\mathcal{O}$.
- $\mathcal{O}$ cannot use incompatible jobs

$$
\{p(n)+1, p(n)+2, \ldots, n-1\} .
$$

- Remaining jobs in $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, p(n)\}$.
- $\mathcal{O}$ must be the best of these two choices!

## Sub-problems

- Let $\mathcal{O}$ be the optimal solution. Two cases to consider. Case 1 job $n$ is not in $\mathcal{O}$. $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, n-1\}$. Case 2 job $n$ is in $\mathcal{O}$.
- $\mathcal{O}$ cannot use incompatible jobs $\{p(n)+1, p(n)+2, \ldots, n-1\}$.
- Remaining jobs in $\mathcal{O}$ must be the optimal solution for jobs $\{1,2, \ldots, p(n)\}$.
- $\mathcal{O}$ must be the best of these two choices!
- Suggests finding optimal solution for sub-problems consisting of jobs $\{1,2, \ldots, j-1, j\}$, for all values of $j$.

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution $(\operatorname{OPT}(0)=0)$.

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution ( $\operatorname{OPT}(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution ( $\operatorname{OPT}(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\text { Case } 1 j \notin \mathcal{O}_{j} \text { : }
$$

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $O P T(j)$ be the value of this solution ( $\operatorname{OPT}(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\text { Case } 1 j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1) .
$$

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $O P T(j)$ be the value of this solution ( $\operatorname{OPT}(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

```
Case \(1 j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1)\).
Case \(2 j \in \mathcal{O}_{j}\) :
```

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution (OPT $(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\begin{aligned}
& \text { Case } 1 \quad j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1) . \\
& \text { Case } 2 j \in \mathcal{O}_{j}: \operatorname{OPT}(j)=v_{j}+\operatorname{OPT}(p(j))
\end{aligned}
$$

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution (OPT $(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\begin{aligned}
& \text { Case } 1 \underset{j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1) .}{\text { Case } 2 j \in \mathcal{O}_{j}: \operatorname{OPT}(j)=v_{j}+\operatorname{OPT}(p(j))} \\
& \qquad \operatorname{OPT}(j)=\max \left(v_{j}+\operatorname{OPT}(p(j)), \operatorname{OPT}(j-1)\right)
\end{aligned}
$$

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution (OPT $(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\begin{aligned}
& \text { Case } 1 \underset{j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1) .}{\text { Case } 2 j \in \mathcal{O}_{j}: \operatorname{OPT}(j)=v_{j}+\operatorname{OPT}(p(j))} \\
& \qquad \operatorname{OPT}(j)=\max \left(v_{j}+\operatorname{OPT}(p(j)), \operatorname{OPT}(j-1)\right)
\end{aligned}
$$

- When does request $j$ belong to $\mathcal{O}_{j}$ ?

## Recursion

- Let $\mathcal{O}_{j}$ be the optimal solution for jobs $\{1,2, \ldots, j\}$ and $\operatorname{OPT}(j)$ be the value of this solution (OPT $(0)=0)$.
- We are seeking $\mathcal{O}_{n}$ with a value of $\operatorname{OPT}(n)$.
- To compute OPT(j):

$$
\begin{aligned}
& \text { Case } 1 j \notin \mathcal{O}_{j}: \operatorname{OPT}(j)=\operatorname{OPT}(j-1) \text {. } \\
& \text { Case } 2 j \in \mathcal{O}_{j}: \operatorname{OPT}(j)=v_{j}+\operatorname{OPT}(p(j)) \\
& \operatorname{OPT}(j)=\max \left(v_{j}+\operatorname{OPT}(p(j)), \operatorname{OPT}(j-1)\right)
\end{aligned}
$$

- When does request $j$ belong to $\mathcal{O}_{j}$ ? If and only if $v_{j}+\operatorname{OPT}(p(j)) \geq \operatorname{OPT}(j-1)$.

## Recursive Algorithm

Compute-Opt ( $j$ )

```
If \(j=0\) then
    Return 0
Else
    Return max \(\left(v_{j}+\right.\) Compute-Opt \((\mathrm{p}(\mathrm{j}))\), Compute-Opt \(\left.(j-1)\right)\)
```

    Endif
    
## Recursive Algorithm

Compute-Opt ( $j$ )

```
If j=0 then
    Return 0
Else
    Return max(vj+Compute-Opt(p(j)), Compute-Opt(j - 1))
```

    Endif
    - Correctness of algorithm follows by induction.

Figure 6.4 An instance of weighted interval scheduling on which the simple ComputeOpt recursion will take exponential time. The values of all intervals in this instance are 1 .

## Example of Recursive Algorithm

Figure 6.2 An instance of weighted interval scheduling with the functions $p(j)$ defined for each interval $j$.

$$
\begin{aligned}
& \operatorname{OPT}(6)= \\
& \operatorname{OPT}(5)= \\
& \operatorname{OPT}(4)= \\
& \operatorname{OPT}(3)= \\
& \operatorname{OPT}(2)= \\
& \operatorname{OPT}(1)= \\
& \operatorname{OPT}(0)=0
\end{aligned}
$$

$\mathrm{OPT}(0)=0$

- Optimal solution is

## Example of Recursive Algorithm

Figure 6.2 An instance of weighted interval scheduling with the functions $p(j)$ defined for each interval $j$.
$\operatorname{OPT}(6)=\max \left(v_{6}+\operatorname{OPT}(p(6)), \operatorname{OPT}(5)\right)=\max (1+\operatorname{OPT}(3), \operatorname{OPT}(5))=8$ $\mathrm{OPT}(5)=\max \left(v_{5}+\mathrm{OPT}(p(j)), \mathrm{OPT}(4)\right)=\max (2+\mathrm{OPT}(3), \mathrm{OPT}(4))=8$ $\operatorname{OPT}(4)=\max \left(v_{4}+\operatorname{OPT}(p(4)), \mathrm{OPT}(3)\right)=\max (7+\mathrm{OPT}(0), \mathrm{OPT}(3))=7$ $\mathrm{OPT}(3)=\max \left(v_{3}+\operatorname{OPT}(p(3)), \mathrm{OPT}(2)\right)=\max (4+\mathrm{OPT}(1), \mathrm{OPT}(2))=6$ $\operatorname{OPT}(2)=\max \left(v_{2}+\operatorname{OPT}(p(2)), \operatorname{OPT}(1)\right)=\max (4+\operatorname{OPT}(0), \operatorname{OPT}(1))=4$ $\operatorname{OPT}(1)=v_{1}=2$
OPT(0) $=0$

- Optimal solution is job 5, job 3, and job 1.

## Running Time of Recursive Algorithm

Compute-Opt ( $j$ )

```
If \(j=0\) then
    Return 0
Else
    Return max \(\left(v_{j}+\right.\) Compute-Opt \((\mathrm{p}(\mathrm{j}))\), Compute-Opt \(\left.(j-1)\right)\)
```

    Endif
    
## Running Time of Recursive Algorithm

Compute-Opt ( $j$ )

```
If j=0 then
    Return 0
    Else
    Return max(vj+Compute-Opt(p(j)), Compute-Opt(j - 1))
    Endif
```

- What is the running time of the algorithm?

## Running Time of Recursive Algorithm

Compute-Opt ( $j$ )

```
If \(j=0\) then
    Return 0
    Else
        Return max \(\left(v_{j}+\right.\) Compute-Opt \((\mathrm{p}(\mathrm{j}))\), Compute-Opt \(\left.(j-1)\right)\)
```

    Endif
    - What is the running time of the algorithm? Can be exponential in $n$.

## Running Time of Recursive Algorithm

Compute-Opt ( $j$ )

```
If j=0 then
    Return 0
    Else
    Return max(vj+Compute-Opt(p(j)), Compute-Opt(j - 1))
    Endif
```

- What is the running time of the algorithm? Can be exponential in $n$.
- When $p(j)=j-2$, for all $j \geq 2$ : recursive calls are for $j-1$ and $j-2$.

Figure 6.4 An instance of weighted interval scheduling on which the simple ComputeOpt recursion will take exponential time. The values of all intervals in this instance
are 1 .

## Memoisation

- Store $\operatorname{OPT}(j)$ values in a cache and reuse them rather than recompute them.

## Memoisation

- Store $\operatorname{OPT}(j)$ values in a cache and reuse them rather than recompute them.

```
M-Compute-Opt (j)
    If \(j=0\) then
        Return 0
    Else if \(M[j]\) is not empty then
        Return \(M[j]\)
    Else
        Define \(M[j]=\max \left(v_{j}+M-C o m p u t e-\operatorname{Opt}(p(j))\right.\), M-Compute-Opt \(\left.(j-1)\right)\)
        Return \(M[j]\)
    Endif
```

## Running Time of Memoisation

```
M-Compute-Opt(j)
    If \(j=0\) then
        Return 0
    Else if \(M[j]\) is not empty then
        Return \(M[j]\)
    Else
        Define \(M[j]=\max \left(v_{j}+M\right.\)-Compute-Opt \((p(j))\), M-Compute-Opt \(\left.(j-1)\right)\)
        Return \(M[j]\)
    Endif
```

- Claim: running time of this algorithm is $O(n)$ (after sorting).

## Running Time of Memoisation

```
M-Compute-Opt(j)
    If \(j=0\) then
        Return 0
    Else if \(M[j]\) is not empty then
        Return \(M[j]\)
    Else
        Define \(M[j]=\max \left(v_{j}+M\right.\)-Compute-Opt \((p(j))\), \(M\)-Compute-Opt \(\left.(j-1)\right)\)
        Return \(M[j]\)
    Endif
```

- Claim: running time of this algorithm is $O(n)$ (after sorting).
- Time spent in a single call to M-Compute-Opt is $O(1)$ apart from time spent in recursive calls.
- Total time spent is the order of the number of recursive calls to M-Compute-Opt.
- How many such recursive calls are there in total?

## Running Time of Memoisation

```
M-Compute-Opt(j)
    If \(j=0\) then
        Return 0
    Else if \(M[j]\) is not empty then
        Return \(M[j]\)
    Else
        Define \(M[j]=\max \left(v_{j}+M-C o m p u t e-O p t(p(j)), M-C o m p u t e-O p t(j-1)\right)\)
        Return \(M[j]\)
    Endif
```

- Claim: running time of this algorithm is $O(n)$ (after sorting).
- Time spent in a single call to M-Compute-Opt is $O(1)$ apart from time spent in recursive calls.
- Total time spent is the order of the number of recursive calls to M-Compute-Opt.
- How many such recursive calls are there in total?
- Use number of filled entries in $M$ as a measure of progress.
- Each time M-Compute-Opt issues two recursive calls, it fills in a new entry in M.
- Therefore, total number of recursive calls is $O(n)$.

## Computing $\mathcal{O}$ in Addition to OPT( $n$ )

## Computing $\mathcal{O}$ in Addition to OPT $(n)$

- Explicitly store $\mathcal{O}_{j}$ in addition to $\operatorname{OPT}(j)$.

## Computing $\mathcal{O}$ in Addition to OPT( $n$ )

- Explicitly store $\mathcal{O}_{j}$ in addition to $\operatorname{OPT}(j)$. Running time becomes $O\left(n^{2}\right)$.

## Computing $\mathcal{O}$ in Addition to OPT( $n$ )

- Explicitly store $\mathcal{O}_{j}$ in addition to $\operatorname{OPT}(j)$. Running time becomes $O\left(n^{2}\right)$.
- Recall: request $j$ belong to $\mathcal{O}_{j}$ if and only if $v_{j}+\operatorname{OPT}(p(j)) \geq \operatorname{OPT}(j-1)$.
- Can recover $\mathcal{O}_{j}$ from values of the optimal solutions in $O(j)$ time.

## Computing $\mathcal{O}$ in Addition to OPT ( $n$ )

- Explicitly store $\mathcal{O}_{j}$ in addition to $\operatorname{OPT}(j)$. Running time becomes $O\left(n^{2}\right)$.
- Recall: request $j$ belong to $\mathcal{O}_{j}$ if and only if $v_{j}+\operatorname{OPT}(p(j)) \geq \operatorname{OPT}(j-1)$.
- Can recover $\mathcal{O}_{j}$ from values of the optimal solutions in $O(j)$ time.

```
Find-Solution(j)
    If j=0 then
        Output nothing
    Else
        If }\mp@subsup{v}{j}{}+M[p(j)]\geqM[j-1] then
            Output j together with the result of Find-Solution(p(j))
        Else
            Output the result of Find-Solution(j-1)
        Endif
    Endif
```

## From Recursion to Iteration

- Unwind the recursion and convert it into iteration.
- Can compute values in $M$ iteratively in $O(n)$ time.
- Find-Solution works as before.

$$
\begin{aligned}
& \text { Iterative-Compute-Opt } \\
& \qquad M[0]=0 \\
& \text { For } j=1,2, \ldots, n \\
& \quad M[j]=\max \left(v_{j}+M[p(j)], M[j-1]\right) \\
& \text { Endfor }
\end{aligned}
$$

## Basic Outline of Dynamic Programming

- To solve a problem, we need a collection of sub-problems that satisfy a few properties:

1. There are a polynomial number of sub-problems.
2. The solution to the problem can be computed easily from the solutions to the sub-problems.
3. There is a natural ordering of the sub-problems from "smallest" to "largest".
4. There is an easy-to-compute recurrence that allows us to compute the solution to a sub-problem from the solutions to some smaller sub-problems.

## Basic Outline of Dynamic Programming

- To solve a problem, we need a collection of sub-problems that satisfy a few properties:

1. There are a polynomial number of sub-problems.
2. The solution to the problem can be computed easily from the solutions to the sub-problems.
3. There is a natural ordering of the sub-problems from "smallest" to "largest".
4. There is an easy-to-compute recurrence that allows us to compute the solution to a sub-problem from the solutions to some smaller sub-problems.

- Difficulties in designing dynamic programming algorithms:

1. Which sub-problems to define?
2. How can we tie together sub-problems using a recurrence?
3. How do we order the sub-problems (to allow iterative computation of optimal solutions to sub-problems)?

## Least Squares Problem

Figure 6.6 A "line of best fit."

- Given scientific or statistical data plotted on two axes.
- Find the "best" line that "passes" through these points.

## Least Squares Problem

Figure 6.6 A "line of best fit."

- Given scientific or statistical data plotted on two axes.
- Find the "best" line that "passes" through these points.
- How do we formalise the problem?

## Least Squares Problem

Figure 6.6 A "line of best fit."

- Given scientific or statistical data plotted on two axes.
- Find the "best" line that "passes" through these points.
- How do we formalise the problem?

Least Squares
INSTANCE: Set $P=\left\{\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{n}, y_{n}\right)\right\}$ of $n$ points. SOLUTION: Line $L: y=a x+b$ that minimises

$$
\operatorname{Error}(L, P)=\sum_{i=1}^{n}\left(y_{i}-a x_{i}-b\right)^{2}
$$

## Least Squares Problem

Figure 6.6 A "line of best fit."

- Given scientific or statistical data plotted on two axes.
- Find the "best" line that "passes" through these points.
- How do we formalise the problem?

LEAST SQUARES
INSTANCE: Set $P=\left\{\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{n}, y_{n}\right)\right\}$ of $n$ points. SOLUTION: Line $L: y=a x+b$ that minimises

$$
\operatorname{Error}(L, P)=\sum_{i=1}^{n}\left(y_{i}-a x_{i}-b\right)^{2}
$$

- Solution is achieved by

$$
a=\frac{n \sum_{i} x_{i} y_{i}-\left(\sum_{i} x_{i}\right)\left(\sum_{i} y_{i}\right)}{n \sum_{i} x_{i}^{2}-\left(\sum_{i} x_{i}\right)^{2}} \text { and } b=\frac{\sum_{i} y_{i}-a \sum_{i} x_{i}}{n}
$$

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines.

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines. Figure 6.8 A set of points that lie approximately on three lines.

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines. Figure 6.8 A set of points that lie approximately on three lines.

- Want to fit multiple lines through $P$.
- Each line must fit contiguous set of $x$-coordinates.
- Lines must minimise total error.

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines. Figure 6.8 A set of points that lie approximately on three lines.

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines. Figure 6.8 A set of points that lie approximately on three lines.

## Segmented Least Squares

INSTANCE: Set $P=\left\{p_{i}=\left(x_{i}, y_{i}\right), 1 \leq i \leq n\right\}$ of $n$ points, $x_{1}<x_{2}<\cdots<x_{n}$
SOLUTION: A integer $k$, a partition of $P$ into $k$ segments $\left\{P_{1}, P_{2}, \ldots, P_{k}\right\}, k$ lines $L_{j}: y=a_{j} x+b_{j}, 1 \leq j \leq k$ that minimise

$$
\sum_{j=1}^{k} \operatorname{Error}\left(L_{j}, P_{j}\right)
$$

- A subset $P^{\prime}$ of $P$ is a segment if $1 \leq i<j \leq n$ exist such that $P^{\prime}=\left\{\left(x_{i}, y_{i}\right),\left(x_{i+1}, y_{i+1}\right), \ldots,\left(x_{j-1}, y_{j-1}\right),\left(x_{j}, y_{j}\right)\right\}$.

## Segmented Least Squares

Figure 6.7 A set of points that lie approximately on two lines.
Figure 6.8 A set of points that lie approximately on three lines.

## Segmented Least Squares

INSTANCE: Set $P=\left\{p_{i}=\left(x_{i}, y_{i}\right), 1 \leq i \leq n\right\}$ of $n$ points, $x_{1}<x_{2}<\cdots<x_{n}$ and a parameter $C>0$.
SOLUTION: A integer $k$, a partition of $P$ into $k$ segments $\left\{P_{1}, P_{2}, \ldots, P_{k}\right\}, k$ lines $L_{j}: y=a_{j} x+b_{j}, 1 \leq j \leq k$ that minimise

$$
\sum_{j=1}^{k} \operatorname{Error}\left(L_{j}, P_{j}\right)+C k
$$

- A subset $P^{\prime}$ of $P$ is a segment if $1 \leq i<j \leq n$ exist such that $P^{\prime}=\left\{\left(x_{i}, y_{i}\right),\left(x_{i+1}, y_{i+1}\right), \ldots,\left(x_{j-1}, y_{j-1}\right),\left(x_{j}, y_{j}\right)\right\}$.

## Example of Segmented Least Squares

$\bigcirc$

Input contains a set of two-dimensional points.

## Example of Segmented Least Squares

Consider the $x$-coordinates of the points in the input.

## Example of Segmented Least Squares

Divide the points into segments; each segment contains consecutive points in the sorted order by $x$-coordinate.

## Example of Segmented Least Squares

Fit the best line for each segment.

## Example of Segmented Least Squares

Illegal solution: black point is not in any segment.

## Example of Segmented Least Squares

Illegal solution: leftmost purple point has $x$-coordinate between last two points in green segment.

## Formulating the Recursion I

- Observation: $p_{n}$ is part of some segment in the optimal solution. This segment starts at some point $p_{i}$.
- Let $O P T(i)$ be the optimal value for the points $\left\{p_{1}, p_{2}, \ldots, p_{i}\right\}$.
- Let $e_{i, j}$ denote the minimum error of any line that fits $\left\{p_{i}, p_{2}, \ldots, p_{j}\right\}$.
- We want to compute $\operatorname{OPT}(n)$.

Figure 6.9 A possible solution: a single line segment fits points $p_{i}, p_{i+1}, \ldots, p_{n}$, and then an optimal solution is found for the remaining points $p_{1}, p_{2}, \ldots, p_{i-1}$.

- If the last segment in the optimal partition is $\left\{p_{i}, p_{i+1}, \ldots, p_{n}\right\}$, then

$$
\operatorname{OPT}(n)=e_{i, n}+C+\operatorname{OPT}(i-1)
$$

## Formulating the Recursion II

- Consider the sub-problem on the points $\left\{p_{1}, p_{2}, \ldots p_{j}\right\}$
- To obtain OPT( $j$ ), if the last segment in the optimal partition is $\left\{p_{i}, p_{i+1}, \ldots, p_{j}\right\}$, then

$$
\operatorname{OPT}(j)=e_{i, j}+C+\operatorname{OPT}(i-1)
$$

## Formulating the Recursion II

- Consider the sub-problem on the points $\left\{p_{1}, p_{2}, \ldots p_{j}\right\}$
- To obtain $\operatorname{OPT}(j)$, if the last segment in the optimal partition is $\left\{p_{i}, p_{i+1}, \ldots, p_{j}\right\}$, then

$$
\mathrm{OPT}(j)=e_{i, j}+C+\mathrm{OPT}(i-1)
$$

- Since $i$ can take only $j$ distinct values,

$$
\operatorname{OPT}(j)=\min _{1 \leq i \leq j}\left(e_{i, j}+C+\operatorname{OPT}(i-1)\right)
$$

- Segment $\left\{p_{i}, p_{i+1}, \ldots p_{j}\right\}$ is part of the optimal solution for this sub-problem if and only if the minimum value of $\operatorname{OPT}(j)$ is obtained using index $i$.

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(j)=\min _{1 \leq i \leq j}\left(e_{i, j}+C+\operatorname{OPT}(i-1)\right)
$$

```
Segmented-Least-Squares( \(n\) )
    Array \(M[0 \ldots n]\)
    Set \(M[0]=0\)
    For all pairs \(i \leq j\)
        Compute the least squares error \(e_{i, j}\) for the segment \(p_{i}, \ldots, p_{j}\)
    Endfor
    For \(j=1,2, \ldots, n\)
        Use the recurrence (6.7) to compute \(M[j]\)
    Endfor
Return \(M[n]\)
```

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(j)=\min _{1 \leq i \leq j}\left(e_{i, j}+C+\operatorname{OPT}(i-1)\right)
$$

```
Segmented-Least-Squares( \(n\) )
    Array \(M[0 \ldots n]\)
    Set \(M[0]=0\)
    For all pairs \(i \leq j\)
        Compute the least squares error \(e_{i, j}\) for the segment \(p_{i}, \ldots, p_{j}\)
    Endfor
    For \(j=1,2, \ldots, n\)
        Use the recurrence (6.7) to compute \(M[j]\)
    Endfor
Return \(M[n]\)
```

- Running time is $O\left(n^{3}\right)$, can be improved to $O\left(n^{2}\right)$.
- We can find the segments in the optimal solution by backtracking.

## RNA Molecules

- RNA is a basic biological molecule. It is single stranded.
- RNA molecules fold into complex "secondary structures."
- Secondary structure often governs the behaviour of an RNA molecule.
- Various rules govern secondary structure formation:

## RNA Molecules

- RNA is a basic biological molecule. It is single stranded.
- RNA molecules fold into complex "secondary structures."
- Secondary structure often governs the behaviour of an RNA molecule.
- Various rules govern secondary structure formation:

1. Pairs of bases match up; each base matches with $\leq 1$ other base.
2. Adenine always matches with Uracil.
3. Cytosine always matches with Guanine.
4. There are no kinks in the folded molecule.
5. Structures are "knot-free".

Figure 6.13 An RNA secondary structure. Thick lines connect adjacent elements of the sequence; thin lines indicate pairs of elements that are matched.

- An RNA molecule is a string $B=b_{1} b_{2} \ldots b_{n}$; each $b_{i} \in\{A, C, G, U\}$.
- A secondary structure on $B$ is a set of pairs $S=\{(i, j)\}$, where $1 \leq i, j \leq n$ and

1. (No kinks.) If $(i, j) \in S$, then $i<j-4$.
2. (Watson-Crick) The elements in each pair in $S$ consist of either $\{A, U\}$ or $\{C, G\}$ (in either order).
3. $S$ is a matching: no index appears in more than one pair.
4. (No knots) If $(i, j)$ and ( $k, I$ ) are two pairs in $S$, then we cannot have $i<k<j<l$.

- The energy of a secondary structure $\propto$ the number of base pairs in it.
- Problem: Compute the largest secondary structure, i.e., with the largest number of base pairs.

## Illegal Secondary Structures

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$.

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, use $\operatorname{OPT}(j-1)$.

## Dynamic Programming Approach

- $\operatorname{OPT}(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, use $\operatorname{OPT}(j-1)$.
2. if $j$ pairs with some $t<j-4$,

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, use $\operatorname{OPT}(j-1)$.
2. if $j$ pairs with some $t<j-4$, knot condition yields two independent sub-problems!

(b)

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

## Dynamic Programming Approach

- $\operatorname{OPT}(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, use $\operatorname{OPT}(j-1)$.
2. if $j$ pairs with some $t<j-4$, knot condition yields two independent sub-problems! OPT $(t-1)$ and ???

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

## Dynamic Programming Approach

- $O P T(j)$ is the maximum number of base pairs in a secondary structure for $b_{1} b_{2} \ldots b_{j}$. $\operatorname{OPT}(j)=0$, if $j \leq 5$.
- In the optimal secondary structure on $b_{1} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, use $\operatorname{OPT}(j-1)$.
2. if $j$ pairs with some $t<j-4$, knot condition yields two independent sub-problems! OPT $(t-1)$ and ???

- Insight: need sub-problems indexed both by start and by end.

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$.

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.
- In the optimal secondary structure on $b_{i} b_{2} \ldots b_{j}$
$\operatorname{OPT}(i, j)=\max ($

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.
- In the optimal secondary structure on $b_{i} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, compute $\operatorname{OPT}(i, j-1)$.
$\operatorname{OPT}(i, j)=\max (\operatorname{OPT}(i, j-1)$,

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.
- In the optimal secondary structure on $b_{i} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, compute $\operatorname{OPT}(i, j-1)$.
2. if $j$ pairs with some $t<j-4$, compute $\operatorname{OPT}(i, t-1)$ and $\operatorname{OPT}(t+1, j-1)$.
$\operatorname{OPT}(i, j)=\max (\operatorname{OPT}(i, j-1)$,

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.
- In the optimal secondary structure on $b_{i} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, compute $\operatorname{OPT}(i, j-1)$.
2. if $j$ pairs with some $t<j-4$, compute $\operatorname{OPT}(i, t-1)$ and $\operatorname{OPT}(t+1, j-1)$.

- Since $t$ can range from $i$ to $j-5$,
$\operatorname{OPT}(i, j)=\max (\operatorname{OPT}(i, j-1)$,

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

1. if $j$ is not a member of any pair, compute $\operatorname{OPT}(i, j-1)$.
2. if $j$ pairs with some $t<j-4$, compute $\operatorname{OPT}(i, t-1)$ and $\operatorname{OPT}(t+1, j-1)$.

- Since $t$ can range from $i$ to $j-5$,
$\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)$

## Correct Dynamic Programming Approach

Figure 6.15 Schematic views of the dynamic programming recurrence using (a) one variable, and (b) two variables.

- $\operatorname{OPT}(i, j)$ is the maximum number of base pairs in a secondary structure for $b_{i} b_{2} \ldots b_{j}$. $\operatorname{OPT}(i, j)=0$, if $i \geq j-4$.
- In the optimal secondary structure on $b_{i} b_{2} \ldots b_{j}$

1. if $j$ is not a member of any pair, compute $\operatorname{OPT}(i, j-1)$.
2. if $j$ pairs with some $t<j-4$, compute $\operatorname{OPT}(i, t-1)$ and $\operatorname{OPT}(t+1, j-1)$.

- Since $t$ can range from $i$ to $j-5$,
$\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)$
- In the "inner" maximisation, $t$ runs over all indices between $i$ and $j-5$ that are allowed to pair with $j$.

## Example of Dynamic Programming Algorithm

| $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $\Theta$ | $-\Theta$ | $-\Theta$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| $A$ | $C$ | $A$ | $U$ | $G$ | $G$ | $C$ | $C$ | $A$ | $U$ | $G$ | $U$ |

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)
$$

- There are $O\left(n^{2}\right)$ sub-problems.
- How do we order them from "smallest" to "largest"?

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)
$$

- There are $O\left(n^{2}\right)$ sub-problems.
- How do we order them from "smallest" to "largest"?
- Note that computing $\operatorname{OPT}(i, j)$ involves sub-problems $\operatorname{OPT}(I, m)$ where $m-l<j-i$.

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)
$$

- There are $O\left(n^{2}\right)$ sub-problems.
- How do we order them from "smallest" to "largest"?
- Note that computing $\operatorname{OPT}(i, j)$ involves sub-problems $\operatorname{OPT}(I, m)$ where $m-l<j-i$.

```
Initialize OPT (i,j)=0 whenever i\geqj-4
For k=5, 6,\ldots,n-1
    For i=1,2,\ldotsn-k
        Set j=i+k
        Compute OPT(i,j) using the recurrence in (6.13)
    Endfor
Endfor
Return OPT(1,n)
```

## Dynamic Programming Algorithm

$$
\operatorname{OPT}(i, j)=\max \left(\mathrm{OPT}(i, j-1), \max _{t}(1+\mathrm{OPT}(i, t-1)+\mathrm{OPT}(t+1, j-1))\right)
$$

- There are $O\left(n^{2}\right)$ sub-problems.
- How do we order them from "smallest" to "largest"?
- Note that computing $\operatorname{OPT}(i, j)$ involves sub-problems $\operatorname{OPT}(I, m)$ where $m-l<j-i$.

```
Initialize OPT (i,j)=0 whenever i\geqj-4
For k=5, 6,\ldots,n-1
    For i=1,2,\ldotsn-k
        Set j=i+k
        Compute OPT(i,j) using the recurrence in (6.13)
    Endfor
Endfor
Return OPT(1,n)
```

- Running time of the algorithm is $O\left(n^{3}\right)$.

- Edit distance model: how many changes must you to make to one string to transform it into another?
- Changes allowed are deleting a letter, adding a letter, changing a letter.

## Edit Distance

- Proposed by Needleman and Wunsch in the early 1970s.
- Input: two strings $x=x_{1} x_{2} x_{3} \ldots x_{m}$ and $y=y_{1} y_{2} \ldots y_{n}$.
- Sequences $\{1,2, \ldots, m\}$ and $\{1,2, \ldots, n\}$ represent positions in $x$ and $y$.

## Edit Distance

- Proposed by Needleman and Wunsch in the early 1970s.
- Input: two strings $x=x_{1} x_{2} x_{3} \ldots x_{m}$ and $y=y_{1} y_{2} \ldots y_{n}$.
- Sequences $\{1,2, \ldots, m\}$ and $\{1,2, \ldots, n\}$ represent positions in $x$ and $y$.
- A matching of these sets is a set $M$ of ordered pairs such that

1. in each pair $(i, j), 1 \leq i \leq m$ and $1 \leq j \leq n$ and
2. no index from $x$ (respectively, from $y$ ) appears as the first (respectively, second) element in more than one ordered pair.

- An index is not matched if it does not appear in the matching.

## Edit Distance

        For i=1,\ldots,m
            Use the recurrence (6.16) to compute A[i,j]
        Endfor
    Endfor
    Return A[m,n]
```

- Running time is $O(m n)$. Space used in $O(m n)$.
- Can compute OPT $(m, n)$ in $O(m n)$ time and $O(m+n)$ space (Hirschberg 1975, Chapter 6.7).
- Can compute alignment in the same bounds by combining dynamic programming with divide and conquer.

## Graph-theoretic View of Sequence Alignment

Figure 6.17 A graph-based picture of sequence alignment.

- Grid graph $G_{x y}$ :
- Rows labelled by symbols in $x$ and columns labelled by symbols in $y$.
- Edges from node $(i, j)$ to $(i, j+1)$ ), to $(i+1, j)$, and to $(i+1, j+1)$.
- Edges directed upward and to the right have cost $\delta$.
- Edge directed from $(i, j)$ to $(i+1, j+1)$ has cost $\alpha_{x_{i+1} y_{j+1}}$.

## Graph-theoretic View of Sequence Alignment

Figure 6.17 A graph-based picture of sequence alignment.

- Grid graph $G_{x y}$ :
- Rows labelled by symbols in $x$ and columns labelled by symbols in $y$.
- Edges from node $(i, j)$ to $(i, j+1)$ ), to $(i+1, j)$, and to $(i+1, j+1)$.
- Edges directed upward and to the right have cost $\delta$.
- Edge directed from $(i, j)$ to $(i+1, j+1)$ has cost $\alpha_{x_{i+1} y_{j+1}}$.
- $f(i, j)$ : minimum cost of a path in $G_{X Y}$ from $(0,0)$ to $(i, j)$.
- Claim: $f(i, j)=\operatorname{OPT}(i, j)$ and diagonal edges in the shortest path are the matched pairs in the alignment.

## Motivation

- Computational finance:
- Each node is a financial agent.
- The cost $c_{u v}$ of an edge $(u, v)$ is the cost of a transaction in which we buy from agent $u$ and sell to agent $v$.
- Negative cost corresponds to a profit.
- Internet routing protocols
- Dijkstra's algorithm needs knowledge of the entire network.
- Routers only know which other routers they are connected to.
- Algorithm for shortest paths with negative edges is decentralised.
- We will not study this algorithm in the class. See Chapter 6.9.

## Problem Statement

- Input: a directed graph $G=(V, E)$ with a cost function $c: E \rightarrow \mathbb{R}$, i.e., $c_{u v}$ is the cost of the edge $(u, v) \in E$.
- A negative cycle is a directed cycle whose edges have a total cost that is negative.
- Two related problems:

1. If $G$ has no negative cycles, find the shortest $s$ - $t$ path: a path of from source $s$ to destination $t$ with minimum total cost.
2. Does $G$ have a negative cycle?

## Problem Statement

- Input: a directed graph $G=(V, E)$ with a cost function $c: E \rightarrow \mathbb{R}$, i.e., $c_{u v}$ is the cost of the edge $(u, v) \in E$.
- A negative cycle is a directed cycle whose edges have a total cost that is negative.
- Two related problems:

1. If $G$ has no negative cycles, find the shortest $s$ - $t$ path: a path of from source $s$ to destination $t$ with minimum total cost.
2. Does $G$ have a negative cycle?

Figure 6.20 In this graph, one can find $s$-t paths of arbitrarily negative cost (by going around the cycle $C$ many times).

## Approaches for Shortest Path Algorithm

1. Dijsktra's algorithm.
2. Add some large constant to each edge.

## Approaches for Shortest Path Algorithm

1. Dijsktra's algorithm. Computes incorrect answers because it is greedy.
2. Add some large constant to each edge. Computes incorrect answers because the minimum cost path changes.

(a)

(b)

Figure 6.21 (a) With negative edge costs, Dijkstra's Algorithm can give the wrong answer for the Shortest-Path Problem. (b) Adding 3 to the cost of each edge will make all edges nonnegative, but it will change the identity of the shortest $s$ - $t$ path.

## Dynamic Programming Approach

- Assume $G$ has no negative cycles.
- Claim: There is a shortest path from $s$ to $t$ that is simple (does not repeat a node)

## Dynamic Programming Approach

- Assume $G$ has no negative cycles.
- Claim: There is a shortest path from $s$ to $t$ that is simple (does not repeat a node) and hence has at most $n-1$ edges.

## Dynamic Programming Approach

- Assume $G$ has no negative cycles.
- Claim: There is a shortest path from $s$ to $t$ that is simple (does not repeat a node) and hence has at most $n-1$ edges.
- How do we define sub-problems?

## Dynamic Programming Approach

- Assume $G$ has no negative cycles.
- Claim: There is a shortest path from $s$ to $t$ that is simple (does not repeat a node) and hence has at most $n-1$ edges.
- How do we define sub-problems?
- Shortest $s$ - $t$ path has $\leq n-1$ edges: how we can reach $t$ using $i$ edges, for different values of $i$ ?
- We do not know which nodes will be in shortest $s-t$ path: how we can reach $t$ from each node in $V$ ?

## Dynamic Programming Approach

- Assume $G$ has no negative cycles.
- Claim: There is a shortest path from $s$ to $t$ that is simple (does not repeat a node) and hence has at most $n-1$ edges.
- How do we define sub-problems?
- Shortest $s$ - $t$ path has $\leq n-1$ edges: how we can reach $t$ using $i$ edges, for different values of $i$ ?
- We do not know which nodes will be in shortest $s-t$ path: how we can reach $t$ from each node in $V$ ?
- Sub-problems defined by varying the number of edges in the shortest path and by varying the starting node in the shortest path.

## Dynamic Programming Recursion

- OPT( $i, v)$ : minimum cost of a $v-t$ path that uses at most $i$ edges.
- $t$ is not explicitly mentioned in the sub-problems.
- Goal is to compute OPT( $n-1, s$ ).

## Dynamic Programming Recursion

- $O P T(i, v)$ : minimum cost of a $v-t$ path that uses at most $i$ edges.
- $t$ is not explicitly mentioned in the sub-problems.
- Goal is to compute OPT( $n-1, s$ ).

Figure 6.22 The minimum-cost path $P$ from $v$ to $t$ using at most $i$ edges.

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.

## Dynamic Programming Recursion

- $O P T(i, v)$ : minimum cost of a $v-t$ path that uses at most $i$ edges.
- $t$ is not explicitly mentioned in the sub-problems.
- Goal is to compute OPT( $n-1, s$ ).

Figure 6.22 The minimum-cost path $P$ from $v$ to $t$ using at most $i$ edges.

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.

1. If $P$ actually uses $i-1$ edges, then $\operatorname{OPT}(i, v)=\operatorname{OPT}(i-1, v)$.
2. If first node on $P$ is $w$, then $\operatorname{OPT}(i, v)=c_{v w}+\operatorname{OPT}(i-1, w)$.

## Dynamic Programming Recursion

- OPT $(i, v)$ : minimum cost of a $v-t$ path that uses at most $i$ edges.
- $t$ is not explicitly mentioned in the sub-problems.
- Goal is to compute OPT( $n-1, s$ ).

Figure 6.22 The minimum-cost path $P$ from $v$ to $t$ using at most $i$ edges.

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.

1. If $P$ actually uses $i-1$ edges, then $\operatorname{OPT}(i, v)=\operatorname{OPT}(i-1, v)$.
2. If first node on $P$ is $w$, then $\operatorname{OPT}(i, v)=c_{v w}+\operatorname{OPT}(i-1, w)$.

$$
\operatorname{OPT}(i, v)=\min \left(\operatorname{OPT}(i-1, v), \min _{w \in V}\left(c_{v w}+\operatorname{OPT}(i-1, w)\right)\right)
$$

Example of Dynamic Programming Recursion $\operatorname{OPT}(i, v)=\min \left(\operatorname{OPT}(i-1, v), \min _{w \in V}\left(c_{w w}+\operatorname{OPT}(i-1, w)\right)\right)$

Example of Dynamic Programming Recursion $\operatorname{OPT}(i, v)=\min \left(\operatorname{OPT}(i-1, v), \min _{w \in V}\left(c_{w w}+\operatorname{OPT}(i-1, w)\right)\right)$

$\begin{array}{llllll}0 & 1 & 2 & 3 & 5\end{array}$

## Alternate Dynamic Programming Formulation

- OPT( $i, v)$ : minimum cost of a $v-t$ path that uses exactly $i$ edges. Goal is to compute

## Alternate Dynamic Programming Formulation

- OPT( $i, v)$ : minimum cost of a $v$ - $t$ path that uses exactly $i$ edges. Goal is to compute

$$
\min _{i=1}^{n-1} \mathrm{OPT}(i, s) .
$$

## Alternate Dynamic Programming Formulation

- OPT( $i, v)$ : minimum cost of a $v-t$ path that uses exactly $i$ edges. Goal is to compute

$$
\min _{i=1}^{n-1} \mathrm{OPT}(i, s) .
$$

- Let $P$ be the optimal path whose cost is OPT $(i, v)$.

## Alternate Dynamic Programming Formulation

- OPT $(i, v)$ : minimum cost of a $v$ - $t$ path that uses exactly $i$ edges. Goal is to compute

$$
\min _{i=1}^{n-1} \mathrm{OPT}(i, s) .
$$

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.
- If first node on $P$ is $w$, then $\operatorname{OPT}(i, v)=c_{v w}+\operatorname{OPT}(i-1, w)$.

## Alternate Dynamic Programming Formulation

- OPT $(i, v)$ : minimum cost of a $v$ - $t$ path that uses exactly $i$ edges. Goal is to compute

$$
\min _{i=1}^{n-1} \mathrm{OPT}(i, s) .
$$

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.
- If first node on $P$ is $w$, then $\operatorname{OPT}(i, v)=c_{v w}+\operatorname{OPT}(i-1, w)$.

$$
\operatorname{OPT}(i, v)=\min _{w \in V}\left(c_{v w}+\operatorname{OPT}(i-1, w)\right)
$$

## Alternate Dynamic Programming Formulation

- OPT( $i, v)$ : minimum cost of a $v-t$ path that uses exactly $i$ edges. Goal is to compute

$$
\min _{i=1}^{n-1} \mathrm{OPT}(i, s) .
$$

- Let $P$ be the optimal path whose cost is $\operatorname{OPT}(i, v)$.
- If first node on $P$ is $w$, then $\operatorname{OPT}(i, v)=c_{v w}+\operatorname{OPT}(i-1, w)$.

$$
\operatorname{OPT}(i, v)=\min _{w \in V}\left(c_{v w}+\operatorname{OPT}(i-1, w)\right)
$$

- Compare the two desired solutions:

$$
\begin{gathered}
\min _{i=1}^{n-1} \operatorname{OPT}(i, s)=\min _{i=1}^{n-1}\left(\min _{w \in V}\left(c_{s w}+\operatorname{OPT}(i-1, w)\right)\right) \\
\operatorname{OPT}(n-1, s)=\min \left(\operatorname{OPT}(n-2, s), \min _{w \in V}\left(c_{s w}+\operatorname{OPT}(n-2, w)\right)\right)
\end{gathered}
$$

## Bellman-Ford Algorithm

$$
\operatorname{OPT}(i, v)=\min \left(\operatorname{OPT}(i-1, v), \min _{w \in V}\left(c_{w w}+\operatorname{OPT}(i-1, w)\right)\right)
$$

```
Shortest-Path ( \(G, s, t\) )
    \(n=\) number of nodes in \(G\)
    Array \(M[0 \ldots n-1, V]\)

```

- Space used is $O\left(n^{2}\right)$. Running time is $O\left(n^{3}\right)$.
- If shortest path uses $k$ edges, we can recover it in $O(k n)$ time by tracing back through smaller sub-problems.

## An Improved Bound on the Running Time

- Suppose $G$ has $n$ nodes and $m \ll\binom{n}{2}$ edges. Can we demonstrate a better upper bound on the running time?

## An Improved Bound on the Running Time

- Suppose $G$ has $n$ nodes and $m \ll\binom{n}{2}$ edges. Can we demonstrate a better upper bound on the running time?

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{v w}+M[i-1, w]\right)\right)
$$

## An Improved Bound on the Running Time

- Suppose $G$ has $n$ nodes and $m \ll\binom{n}{2}$ edges. Can we demonstrate a better upper bound on the running time?

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{v w}+M[i-1, w]\right)\right)
$$

- $w$ only needs to range over neighbours of $v$.
- If $n_{v}$ is the number of neighbours of $v$, then in each round, we spend time equal to

$$
\sum_{v \in V} n_{v}=
$$

## An Improved Bound on the Running Time

- Suppose $G$ has $n$ nodes and $m \ll\binom{n}{2}$ edges. Can we demonstrate a better upper bound on the running time?

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{v w}+M[i-1, w]\right)\right)
$$

- $w$ only needs to range over neighbours of $v$.
- If $n_{v}$ is the number of neighbours of $v$, then in each round, we spend time equal to

$$
\sum_{v \in V} n_{v}=m
$$

- The total running time is $O(m n)$.

## Improving the Memory Requirements

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{w w}+M[i-1, w]\right)\right)
$$

- The algorithm uses $O\left(n^{2}\right)$ space to store the array $M$.

## Improving the Memory Requirements

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{w w}+M[i-1, w]\right)\right)
$$

- The algorithm uses $O\left(n^{2}\right)$ space to store the array $M$.
- Observe that $M[i, v]$ depends only on $M[i-1, *]$ and no other indices.

## Improving the Memory Requirements

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{v w}+M[i-1, w]\right)\right)
$$

- The algorithm uses $O\left(n^{2}\right)$ space to store the array $M$.
- Observe that $M[i, v]$ depends only on $M[i-1, *]$ and no other indices.
- Modified algorithm:

1. Maintain two arrays $M$ and $M^{\prime}$ indexed over $V$.
2. At the beginning of each iteration, copy $M$ into $M^{\prime}$.
3. To update $M$, use

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

## Improving the Memory Requirements

$$
M[i, v]=\min \left(M[i-1, v], \min _{w \in V}\left(c_{w w}+M[i-1, w]\right)\right)
$$

- The algorithm uses $O\left(n^{2}\right)$ space to store the array $M$.
- Observe that $M[i, v]$ depends only on $M[i-1, *]$ and no other indices.
- Modified algorithm:

1. Maintain two arrays $M$ and $M^{\prime}$ indexed over $V$.
2. At the beginning of each iteration, copy $M$ into $M^{\prime}$.
3. To update $M$, use

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

- Claim: at the beginning of iteration $i, M$ stores values of $\operatorname{OPT}(i-1, v)$ for all nodes $v \in V$.
- Space used is $O(n)$.

## Computing the Shortest Path: Algorithm

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

- How can we recover the shortest path that has cost $M[v]$ ?

## Computing the Shortest Path: Algorithm

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{r w}+M^{\prime}[w]\right)\right)
$$

- How can we recover the shortest path that has cost $M[v]$ ?
- For each node $v$, maintain $f(v)$, the first node after $v$ in the current shortest path from $v$ to $t$.
- To update $f(v)$, if we ever set $M[v]$ to $\min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)$, set $f(v)$ to be the node $w$ that attains this minimum.
- At the end, follow $f(v)$ pointers from $s$ to $t$.

## Example of Maintaining Pointers

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in N_{v}}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

## Example of Maintaining Pointers

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in N_{v}}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

## Example of Maintaining Pointers

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in N_{v}}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

## Example of Maintaining Pointers

$$
M[v]=\min \left(M^{\prime}[v], \min _{w \in N_{v}}\left(c_{v w}+M^{\prime}[w]\right)\right)
$$

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[r], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.
- Suppose we set $f(v)=w$. Between this assignment and the assignment of $f(v)$ to some other node, $M[v] \geq c_{v w}+M[w]$ (because $M[w]$ may itself decrease).

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.
- Suppose we set $f(v)=w$. Between this assignment and the assignment of $f(v)$ to some other node, $M[v] \geq c_{v w}+M[w]$ (because $M[w]$ may itself decrease).
- Let $v_{1}, v_{2}, \ldots v_{k}$ be the nodes in $C$ and assume that $\left(v_{k}, v_{1}\right)$ is the last edge to have been added.
- What is the situation just before this addition?

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.
- Suppose we set $f(v)=w$. Between this assignment and the assignment of $f(v)$ to some other node, $M[v] \geq c_{v w}+M[w]$ (because $M[w]$ may itself decrease).
- Let $v_{1}, v_{2}, \ldots v_{k}$ be the nodes in $C$ and assume that $\left(v_{k}, v_{1}\right)$ is the last edge to have been added.
- What is the situation just before this addition?
- $M\left[v_{i}\right]-M\left[v_{i+1}\right] \geq c_{v_{i} v_{i+1}}$, for all $1 \leq i<k-1$.
- $M\left[v_{k}\right]-M\left[v_{1}\right]>c_{v_{k} v_{1}}$.

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.
- Suppose we set $f(v)=w$. Between this assignment and the assignment of $f(v)$ to some other node, $M[v] \geq c_{v w}+M[w]$ (because $M[w]$ may itself decrease).
- Let $v_{1}, v_{2}, \ldots v_{k}$ be the nodes in $C$ and assume that $\left(v_{k}, v_{1}\right)$ is the last edge to have been added.
- What is the situation just before this addition?
- $M\left[v_{i}\right]-M\left[v_{i+1}\right] \geq c_{v_{i} v_{i+1}}$, for all $1 \leq i<k-1$.
- $M\left[v_{k}\right]-M\left[v_{1}\right]>c_{v_{k} v_{1}}$.
- Adding all these inequalities, $0>\sum_{i=1}^{k-1} c_{v_{i} v_{i+1}}+c_{v_{k} v_{1}}=\operatorname{cost}$ of $C$.

## Computing the Shortest Path: Cycles in $P$

$M[v]=\min \left(M^{\prime}[v], \min _{w \in V}\left(c_{v w}+M^{\prime}[w]\right)\right)$

- Claim: If $P$ has a cycle $C$, then $C$ has negative cost.
- Suppose we set $f(v)=w$. Between this assignment and the assignment of $f(v)$ to some other node, $M[v] \geq c_{v w}+M[w]$ (because $M[w]$ may itself decrease).
- Let $v_{1}, v_{2}, \ldots v_{k}$ be the nodes in $C$ and assume that ( $v_{k}, v_{1}$ ) is the last edge to have been added.
- What is the situation just before this addition?
- $M\left[v_{i}\right]-M\left[v_{i+1}\right] \geq c_{v_{i} v_{i+1}}$, for all $1 \leq i<k-1$.
- $M\left[v_{k}\right]-M\left[v_{1}\right]>c_{v_{k} v_{1}}$.
- Adding all these inequalities, $0>\sum_{i=1}^{k-1} c_{v_{i} v_{i+1}}+c_{v_{k} v_{1}}=\operatorname{cost}$ of $C$.
- Corollary: if $G$ has no negative cycles that $P$ does not either.

## Computing the Shortest Path: Paths in $P$

- Let $P$ be the pointer graph upon termination of the algorithm.
- Consider the path $P_{v}$ in $P$ obtained by following the pointers from $v$ to $f(v)=v_{1}$, to $f\left(v_{1}\right)=v_{2}$, and so on.

## Computing the Shortest Path: Paths in $P$

- Let $P$ be the pointer graph upon termination of the algorithm.
- Consider the path $P_{v}$ in $P$ obtained by following the pointers from $v$ to $f(v)=v_{1}$, to $f\left(v_{1}\right)=v_{2}$, and so on.
- Claim: $P_{v}$ terminates at $t$.

## Computing the Shortest Path: Paths in $P$

- Let $P$ be the pointer graph upon termination of the algorithm.
- Consider the path $P_{v}$ in $P$ obtained by following the pointers from $v$ to $f(v)=v_{1}$, to $f\left(v_{1}\right)=v_{2}$, and so on.
- Claim: $P_{v}$ terminates at $t$.
- Claim: $P_{v}$ is the shortest path in $G$ from $v$ to $t$.

## Bellman-Ford Algorithm: One Array

$$
M[v]=\min \left(M[v], \min _{w \in V}\left(c_{v w}+M[w]\right)\right)
$$

- We can prove algorithm's correctness in this case as well.

## Bellman-Ford Algorithm: Early Termination

$$
M[v]=\min \left(M[v], \min _{w \in V}\left(c_{v w}+M[w]\right)\right)
$$

- In general, after $i$ iterations, the path whose length is $M[v]$ may have many more than $i$ edges.

## Bellman-Ford Algorithm: Early Termination

$$
M[v]=\min \left(M[v], \min _{w \in V}\left(c_{v w}+M[w]\right)\right)
$$

- In general, after $i$ iterations, the path whose length is $M[v]$ may have many more than $i$ edges.
- Early termination: If $M$ does not change after processing all the nodes, we have computed all the shortest paths to $t$.
